Abstract

Part 1:

Transition-metal-catalyzed direct transformations of aromatic C-H bonds are emerging as valuable tools in organic synthesis. These reactions are attractive because they allow for inherently efficient construction of organic building blocks by minimizing the pre-activation of substrates. Of these processes, direct arylation has recently received much attention due to the importance of the biaryl core in medicinal and materials chemistry. Also, alkyne hydroarylation has garnered interest because it allows for the atom-economical synthesis of functionalized alkenes directly from simple arenes and alkynes. Described in this thesis are number of advancements in these areas.

First, palladium catalyzed direct arylation of azine N-oxides using synthetically important aryl triflates is described. Interesting reactivity of aryl triflates compared to aryl bromides was uncovered and exploited in the synthesis of a compound that exhibits antimalarial and antimicrobial activity. Also reported is the efficient, direct arylation enabled (formal) synthesis of six thiophene based organic electronic materials in high yields using simple starting materials. Additionally, the site-selective direct arylation of both $sp^2$ and $sp^3$ sites on azine N-oxide substrates is described. The arylation reactions are carried out in either a divergent manner or a sequential manner and is applied to the synthesis of the natural products, Papaverine and Crykonisine. Mechanistic investigations point towards the intimate involvement of the base in the mechanism of these reactions.

Next, the rhodium(III)-catalyzed hydroarylation of internal alkynes is described. Good yields are obtained for a variety of alkynes and arenes with excellent regioselectivity for
unsymmetrically substituted alkynes. Mechanistic investigations suggest that this reaction proceeds through arene metalation with the cationic rhodium catalyst, which enables challenging intermolecular reactivity.

**Part 2:**

Access to single enantiomer compounds is a fundamental goal in organic chemistry and despite remarkable advances in enantioselective synthesis, their preparation remains a challenge. Kinetic resolution of racemic products is an important method to access enantioenriched compounds, especially when alternative methods are scarce. Described in this thesis is the resolution of tertiary and secondary alcohols, which arise from ketone and aldehyde aldol additions. The method is technically simple, easily scalable, and provides tertiary and secondary alcohols in high enantiomeric ratios. A rationale for the unique reactivity/selectivity associated with (1S,2R)-N-methylephedrine in the resolution is proposed.

Organocatalysis is a rapidly developing, powerful field for the construction of enantioenriched organic molecules. Described here is a complimentary class of organocatalysis using simple aldehydes as temporary tethers to perform challenging formally intermolecular reactions at room temperature. This strategy allows for the enantioselective, intermolecular cope-type hydroamination of allylic amines with hydroxyl amines. Also, interesting catalytic reactivity for dichloromethane is revealed.
Acknowledgements

Firstly, I would like to thank my beautiful and loving wife Christina. I met Christina my first week here in Ottawa and is the only person who has been there for the entire duration of my PhD. She has put up with my many late nights and weekends in the lab as well as seemingly endless chemistry discussions when together with other chemists. I could not have done it without your tireless love and support. Also, thank you for your help with putting this thesis together.

Fagnou Factory, I couldn’t imagine a better group of people with whom to do chemistry. You have fostered an atmosphere of hard work and learning all while having lots of fun. Nicole and Sophie, thank you for welcoming me to the group as a member of the original ketene dream team. Marc, J.P. and Sherbrookers Elisia, Megan and L-train it was a pleasure to work with you. Chris, thanks for the help on the triflate project. Shoresy, thanks for all the laughs, keep it up in San Fran. Olivier, thanks for putting up with my poor desk habits. Don’t let Malcolm be too bad of an influence on you. Malcolm, it was great having you around the lab. Thanks for your infectious passion for knowing the chemistry literature in detail. Marieke, thanks for the help on the hydroarylation project. DLee, Chrisitna and Lina it great working with you, good luck in Toronto. Ivan, keep pumping iron. Moe, you are a hard working and gifted scientist. Good luck in future endeavours. Ho-Yan, thanks for putting up with me as a bench buddy, good luck in Alberta. Dan Black, thanks for introducing me to gazebo unit. Ben, thanks for the good times and great discussions at Mason’s. Sophie, you are one of the brightest and most talented chemists I know. I will follow your career with interest. LC and Dave, your mentorship and passion for chemistry has truly shaped my own ability as a scientist. I look forward to keeping in touch with you. Tom, you are one of the genuinely nicest people I know.
David, you are the CMD master. I’ve been working with you for 4.5 years, its been great, keep in touch. Nic, you immediately impacted our group for the better the day you joined. Your great attitude, intellect and willingness to learn will serve you well. Thank you for being the sole editor for this thesis, it is greatly appreciated.

Thanks to the Beauchemin group for welcoming me into their group towards the end of my PhD. You have made the last few months of my time here great. Specifically I would like to thank Mel for allowing me the opportunity to contribute to the project she was working on.

To everyone who I have battled on the foosball table: Dave, David, Ben, Dan, Nic Tom, Guillaume, Gab Thank-you. Foosball was an integral part of PhD experience. Keep up the continuous flow. To bad I always won the games the counted!

There have some challenging times during the past few years. I would like to the entire community for their support after Keith’s passing. Thanks to Betty who really took care of our group. Thanks to the entire faculty and staff in the chemistry department at the University of Ottawa. Thanks to the Fagnou Factory for supporting each other during this time while still publishing high quality research. I know Keith would be proud. Special thanks to Dave and Ben who played critical leadership roles during this difficult period.

I would like to thank André, who stepped up in big way to act as my supervisor. I spent many hours in André’s office discussing chemistry and life in general. He gave of his time even when I was not working directly on his research. I thank you for giving of your time generously and for mentorship which I hope to continue to enjoy.

Thank you to family and friends. To my parents, brothers and sisters thank you for your support and interest even when my explanations of what I did didn’t make much sense.
Finally I would like to thank Keith. I count myself lucky to be one of the few people Keith had the chance to mentor during his short time. His mentorship, attitude, passion for science and dedication to his family have shaped not only who I am as scientist but also as a person.

Direct Arylation in Biaryl Synthesis

1.1 Introduction

The biaryl motif is featured prominently in a variety of chemistries including pharmaceutical and materials chemistry. The synthesis of biaryls was revolutionized in the 70’s and 80’s, which saw significant advances in the area of palladium catalyzed cross-coupling reactions. These reactions involve the coupling of aryl organometallic reagents (Ar-MgX, Ar-ZnX, Ar-SnR₃, Ar-B(OR)₂, Ar-SiR₃) with aryl halides. This work was recently recognized with a Nobel Prize, which was awarded to Richard Heck, Ei-ichi Negishi and Akira Suzuki for “palladium-catalyzed cross couplings in organic synthesis.” With these advances, biaryls can now be prepared routinely in high yields under mild conditions with broad functional group tolerance. One might think that the field of biaryl synthesis is mature and there is little work left to be done. However, when evaluating the

overall efficiency of reactions, one must not only consider the yield of the product, but also the availability and the synthetic steps required to produce the starting materials. In particular, the use of any functional group which does not appear in the final product can be considered inefficient. It is clear then that even state-of-the-art coupling reactions, which employ two pre-activated components, have inefficiencies inherent in the reaction design. Primarily the organometallic component is particularly problematic because it requires several synthetic steps to prepare, generates a stoichiometric amount of metal waste, is often toxic, difficult to handle, expensive or unavailable.

An emerging alternative to these cross-coupling methods which has received increased attention in recent years is direct arylation, in which one of the pre-activated components, usually the organometallic, is replaced by a simple arene (Scheme 1.1).\(^3\) This strategy

\[ \text{Contemporary Cross-Coupling} \]

\[ \begin{align*}
\text{M} & \text{= Sn}(R^1)^2, \\
\text{B}(OR^2)^2, \\
\text{MgX}, \\
\text{etc.} \\
\end{align*} \]

\[ \begin{align*}
\text{R}^1 & \text{M} \rightarrow \text{X} \\
\text{R}^2 & \text{catalyst} \rightarrow \text{R}^1 \text{M} - \text{X} \\
\end{align*} \]

\[ \text{Direct Arylation} \]

\[ \begin{align*}
\text{H} & \text{= Cl, Br, I, } \text{OSO}_2R^5 \\
\end{align*} \]

\[ \begin{align*}
\text{R}^1 & \text{R}^2 \\

\text{H} & \text{X} \\
\end{align*} \]

\text{Scheme 1.1 – Contemporary Cross-Coupling vs. Direct Arylation}

provides a more efficient synthetic route to biaryl molecules as it eliminates the need for an organometallic reagent and gives a halo-acid as its only stoichiometric by-product.

1.2 Direct Arylation of Heterocycles

Since the first examples of direct arylation the scope, utility and understanding of the reaction has increased dramatically. These advances have been extensively reviewed and therefore will not be discussed here. However, relevant to the chemistry in this thesis is a discussion of palladium-catalyzed intermolecular direct arylation reactions of heterocycles and the mechanism of the transformation which will be presented in the sections to follow.

1.2.1 Direct Arylation of Electron-Rich Heterocycles

For many years electron-rich heterocycles have been at the forefront of direct arylation research. Contributing to this is the high regioselectivities typically observed with electron-rich heterocycles which was originally attributed to the nucleophilicity of the arenes. Although, a concerted metalation-deprotonation mechanism can also explain the observed regioselectivities (vide infra).

The first catalytic example of a palladium-catalyzed intermolecular direct arylation reaction was reported in 1982 by Nakamura. The reported conditions use 10 mol% of palladium acetate to accomplish the direct arylation of an isoxazole with iodobenzene under basic conditions (Scheme 1.2). Following other early examples, Ohta and co-workers described the arylation of indoles with chloropyrazines in 1989. Then, in 1990, Ohta published a second report on the direct arylation of thiophenes and furans in

---

synthetically useful yields. Also, Miura has made significant contributions by describing the direct arylation of other electron-rich heterocycles. In 1998, he reported the arylation of imidazoles, oxazoles and thiazoles with yields varying from 43-83\%.

\[ \text{Scheme 1.2} \] – Early Reports of Palladium-Catalyzed Intermolecular Direct Arylation

Since these early reports, the scope of this reaction has been expanded to include many types of electron-rich heterocycles such as indoles, indolazenes, pyrroles, (benz)oxazoles, (benzo)thiazoles, (benzo)thiophenes, (benz)imidazoles, (benzo)furans among others (Scheme 1.3). Additional advancements have also been made with respect to improving the scope of aryl halides employed, the reaction yields and selectivities.

Scheme 1.3 – Examples of Electron-Rich Heteroarenes Employed in Direct Arylation

Reaction conditions vary widely but generally include: catalytic palladium acetate, carbonate base (K$_2$CO$_3$, NaHCO$_3$, Cs$_2$CO$_3$ etc.) and a high boiling solvent (DMF, DMA, PhMe, dioxane etc.). Phosphine ligands (PCy$_3$, PrBu$_2$Me, biaryl phosphines, PPh$_3$ etc.) are often used but not necessarily in all cases. A pivalic acid additive, which was pioneered by our group$^9$ and others$^{10}$ has proved to be beneficial in many cases. Given the wide range of conditions reported, our group has also pursued a set of reaction conditions that would be applicable across a wide range of heterocycles. This would simplify the reaction screening/literature search process when trying a direct arylation reaction on a new heterocycle. The reported conditions feature low catalyst loading (1-2 mol% Pd(OAc)$_2$), a 1:1 stoichiometry and applicability to a wide range of heterocycles.$^{11}$ The reported conditions applied to the direct arylation of a range of heterocycles are outlined in Scheme 1.4.

---

1.2.2 Direct Arylation of Electron-Poor Heterocycles

The mechanistic proposal put forth for most direct arylation reactions attributed the reactivity of electron-rich heteroarenes to their inherent nucleophilicity. With this mechanistic proposal came the assumption that electron-poor arenes would be poor substrates due to their lack of nucleophilicity. However, in 2006 our group reported the direct arylation of highly electron deficient pentafluorobenzenes (Scheme 1.5).\(^\text{12}\)

**Scheme 1.5 – Direct Arylation of Pentafluorobenzene**

---

This work was related to earlier independent work by the Echavarren group who reported that an intramolecular direct arylation was actually faster with more electron withdrawing substituents. The effectiveness of electron-deficient arenes as substrates for direct arylation lead to a re-evaluation of the mechanism and a proton abstraction (also called concerted metatalation-deprotonation) mechanism was proposed which will be discussed in the following section.

This concept has also been applied to the direct arylation of various electron-poor heterocycles. Examples of compatible electron-poor heterocycles are outlined in Scheme 1.6. Our group has reported a series of azine N-oxide substrates that are suitable for direct arylation.\textsuperscript{13} Charette and co-workers have described a similar strategy which employs N-iminopyridinium ylides.\textsuperscript{14} Unactivated pyridine substrates have been arylated under rhodium catalysis as reported by Bergman and Ellman.\textsuperscript{15}

![Scheme 1.6 – Examples of Electron-Poor Heteroarenes Employed in Direct Arylation](image)

preactivation of the pyridine component, it also requires substitution at the 2 position of pyridine. Finally the Daugulis group has reported the copper-catalyzed direct arylation of acidic substrates including free diazines and pyridine N-oxide.  

1.2.3 Mechanistic Considerations for Direct Arylation

Pertinent the chemistry reported in the following three chapters of this thesis is a discussion of the mechanism of direct arylation. A general catalytic cycle is outlined in Scheme 1.7. Following catalyst initiation, the first step of the catalytic cycle is oxidative insertion of Pd(0) catalyst into the aryl halide bond. The next step is cleavage of the C-H of the simple arene with loss of HX. Finally, reductive elimination yields the biaryl product and regenerated the active Pd(0) catalyst. Of these steps in the catalytic cycle the oxidative insertion and reductive elimination steps are relatively well understood. Conversely, the C-H bond cleavage step is less understood and has been the subject of debate in recent years and warrants further discussion.

Scheme 1.7 – General Catalytic Cycle for Direct Arylation

---

There are four main possibilities that have been put forward as a mechanistic possibility for the C-H bond cleaving step (Scheme 1.8). The carbo-palladation (also called Heck-type) pathway involves the syn-addition of the aryl-palladium bond across the arene to be functionalized. Although the subsequent anti-β-hydride elimination is unlikely, an isomerisation through a π-allyl intermediate followed by syn-β-hydride elimination is possible. Also, in rare cases, the oxidative insertion of a Pd(II) species into a C-H bond of an arene has been proposed. A double reductive elimination would follow to yield the biaryl product and regenerate the catalytically active Pd(0) species.

The most common mechanism that is proposed, especially for electron-rich heterocycles, is electrophilic palladation. An electrophilic palladation or electrophilic aromatic substitution (S$_{E}$Ar) type process involves the nucleophilic attack of an electron-rich arene on an electrophilic Pd(II) species forming a Wheland intermediate. Deprotonation followed by reductive elimination would give the biaryl product and regenerate the active catalyst. The last mechanism, which has received increased attention in recent years, is concerted metalation-deprotonation (CMD).

---

rationalize the reactivity of electron deficient substrates where it was thought that an electrophilic palladation reaction was not possible. However CMD has also been used to validate experimental outcomes from a wide range or arenes including electron-rich substrates. The CMD occurs with simultaneous cleavage of the C-H bond and formation of the new C-Pd bond with loss of HX. While the CMD pathway may resemble an interrupted Wheland intermediate, there is little build-up of carbocation character or loss of aromaticity in the CMD transition state.

Scheme 1.8 – Mechanistic Possibilities for C-H Bond Cleavage

The concerted metalation-deprotonation mechanism for arene C-H bond cleavage has been applied to stoichiometric systems dating as far back as 1955. With the increasing utility of direct arylation as a synthetic tool has come a re-evaluation of CMD in this catalytic context. Our group among others have proposed the CMD pathway for catalytic C-H bond functionalization reactions. Some of these reports suggest that C-H bond acidity may be the governing factor in determining reactivity and selectivity. However, it has been demonstrated that both nucleophilicity and C-H bond acidity may play an important role.

The ambiguity of the role of nucleophilicity and C-H acidity prompted our group to carry out a distortion/interaction analysis using DFT calculations (Scheme 1.9). In this analysis, the individual energies of distortion ($E_{dist}(PdL)$ and $E_{dist}(ArH)$) represents the energetic cost associated with distorting the ground state conformation of reactants to the conformation required for the CMD transition state (I $\rightarrow$ III and II $\rightarrow$ IV). The energy of interaction ($E_{int}$) represents the energy gained from bringing the two distorted components together (III + IV $\rightarrow$ V). The overall activation energy ($\Delta E^\ddagger$) is obtained by simply summing the energy loss ($E_{dist}$) and energy gain ($E_{int}$). The analysis allows the contribution of each variable to be obtained for an electronically diverse set of arenes.

$E_{int}$ values seem to correlate well electron density and therefore nucleophilicity of the

arene. While $E_{\text{dist}}(\text{ArH})$ correlate often, but is not necessarily governed by, C-H bond acidity. Representative examples are shown in scheme 1.9. The electron-rich imidazopyrimidine suffers from a high energy loss from the $E_{\text{dist}}(\text{ArH})$ value (42.2 kcal/mol). This is offset by a large energy gain from the $E_{\text{int}}$ value (-49.4 kcal/mol) which is expected from a nucleophilic arene. Pentafluorobenzene is, in contrast, a relatively electron-poor arene and yet has very similar $\Delta E^\ddagger$ value to the

![Scheme 1.9 – Distortion/Interaction Analysis for CMD Transition State](image)

*values in kcal/mol
electron rich arene (11.1 vs. 11.9 kcal/mol). While pentafluorobenzene has a lower energy gain from the $E_{int}$ value (-32.2 kcal/mol), due to poor electron density, it also requires less energy to distort the C-H bond of the arene (28.8 kcal/mol). Therefore, these arenes have similar $\Delta E^\dagger$ values, but for different reasons: imidazopyrimidine benefits from a large energy of interaction gain and pentafluorobenzene benefits from a low energy of distortion. Simple benzene, a challenging direct arylation substrate, suffers both a high energy of distortion (44.6 kcal/mol) and low energy of interaction gain (-35.3 kcal/mol).
Direct Arylation of Azine N-Oxides With Aryl Triflates

2.1 Introduction

As mentioned previously, biaryl compounds represent an important class of molecule. Specifically, the 2-aryl azine motif features prominently in ligand, medicinal and materials chemistry. Transition metal catalyzed cross coupling reactions of aryl halides with aryl organometallics such as Suzuki, Stille and Negishi reactions represent some of the most important methods for synthesizing biaryl compounds. However, the requirement for substrate pre-activation renders the overall process inefficient and uneconomical. An emerging alternative to these methods which has received increased attention in recent years is direct arylation, in which one of the pre-activated components,

25 A significant portion of the work described in this chapter has been published in the form of an article, see: Schipper, D. J.; El-Salfiti, M.; Whipp, C. J.; Fagnou, K. Tetrahedron 2009, 65, 4977.
usually the organometallic, is replaced by a simple arene.\textsuperscript{28} Although direct arylation reactions have been investigated thoroughly with use of halides, there are few reports employing the use of aryl triflates.\textsuperscript{29} Triflates, while often too expensive and impractical for large scale synthesis, are still an important class of electrophile because they provide unique advantages over the more traditional bromides or iodides (Scheme 2.1). The aryl halide bond is relatively weak and therefore labile under many reaction conditions,

```

\textbf{Scheme 2.1 – Advantages of Aryl Triflates}

rendering them difficult to carry through multiple synthetic steps. Moreover, installation of halides usually requires harsh conditions which may not be compatible with a complex molecule in the late stages of a synthesis. Conversely, protected phenols are robust and conditions for triflate installation are mild. Thus, aryl triflates are ideally suited for introduction in the late stage of a synthetic sequence.

Applications of aryl triflates in the context of direct arylation are illustrated in Scheme 2.2. The first report came from the Rice group who described a palladium-catalyzed intramolecular direct arylation to form fluoranthenes and benzofluoranthenes.\(^\text{30}\) Other intramolecular examples include a report from the Suzuki group who used direct arylation as a key step in the synthesis of gilvocarcin V.\(^\text{31}\) Steglich and co-workers described the synthesis arcyriacyanin A, which required the use of an aryl triflate because the analogous bromo derivative could not be synthesized.\(^\text{32}\) Bringmann \textit{et al.} employed direct arylation to synthesize lactone-bridged ternapthyl.\(^\text{33}\) Again, when the bromo derivative failed, the triflate gave adequate results. The Harayama group used aryl triflate to cyclize amide derivatives using direct arylation to form the corresponding phenanthridone.\(^\text{34}\)

Examples of intermolecular direct arylation which employ aryl triflates are outlined in Scheme 2.3. A group at Boehringer Ingelheim used an aryl triflate for the direct arylation of oxazole to make an HIV-1 reverse transcriptase inhibitor.\textsuperscript{35} Miura has

established arylation conditions for benzamides using triflates.\textsuperscript{36} Also, the Doucet group has reported arylation of a range of electron rich heterocycles with aryl triflates.\textsuperscript{37}

\textbf{Scheme 2.3} – Intermolecular Direct Arylation with Aryl Triflates

Our group has previously reported the palladium catalyzed direct arylation of pyridine and diazine \textit{N}-oxides using a wide range of aryl halides.\textsuperscript{38} Described in this chapter is: (1) an operationally simple catalyst system for the direct arylation of azine \textit{N}-oxide substrates employing aryl triflates, (2) a sequential arylation to yield deferentially di-arylated products that takes advantage of the increased propensity of aryl triflates to induce diarylation, (3) the scope and regioselectivity of arylation on a range of 3-substituted azine \textit{N}-oxides, and (4) the application of this method to the synthesis of an antimalarial and antimicrobial compound.

2.2 Results and Discussion

We began our study by comparing the reactivity of aryl bromides to aryl triflates under our previously established conditions (Scheme 2.4).\textsuperscript{38e} The aryl bromide gave a 76% yield while the aryl triflate resulted in only 14% yield of the desired product. The diminished yields with triflates prompted us to reinvestigate the reaction conditions.

**Scheme 2.4 – Comparison of Aryl Bromides with Aryl Triflates**

An optimization study commenced using pyridine $N$-oxide and $p$-tolyl trifluoromethanesulfonate. This study revealed that, unlike reactions employing aryl bromide substrates, diarylation of the $N$-oxide substrate was a significant challenge with aryl triflates, leading to diminished yields. An evaluation of the various reaction variables lead to two optimized reaction conditions (Scheme 2.5). The first set of conditions was found to minimize diarylation side products thus maximizing the yield of the monoarylation product. This method employs the use of tricyclohexylphosphine as the ligand, Rb$_2$CO$_3$ as the base, and 40 mol% pivalic acid in toluene (0.15 M) at 100 °C for 15 hours (Conditions A). The second set of conditions, which result in increased reactivity, were developed to maximize yields with substrates for which diarylation is not problematic. This method makes use of di-$t$-butylmethylphosphine as the ligand, K$_2$CO$_3$ as the base, with 30 mol% pivalic acid in toluene (0.5 M) at 110 °C for 15 hours.
(Conditions B). The increased reactivity of this system could be partially due to the less sterically demanding nature of the P(tBu₂)Me compared to that of the PCy₃ ligand.

**Scheme 2.5** – Optimized Arylation Conditions for Aryl Triflates

Illustrative examples for reaction with aryl triflates under the two different reaction conditions are outlined in Table 2.1. The arylation proceeds with 89 to 91% yield with 2 to 2.5 equivalents of pyridine N-oxide respectively (Table 2.1, entries 3-4). If less pyridine N-oxide is used diminished yields of 51 to 65% are noted (Table 2.1, entries 1-2). Lower yields of 38 to 59% are obtained with substitution of electron-donating or electron-withdrawing groups at the 4-position (Table 2.1, entries 9-11), although low solubility of these substrates could explain diminished yields. Also, the reaction proceeds well with electron rich aryl triflates (Table 2.1, entries 6, 13 and 26).

Diazine N-oxides are also compatible with the arylation. Pyridazine N-oxide is arylated in 99% when using Conditions B (Table 2.1, entry 15). Pyrazine N-oxide gives 43-99% yield (Table 2.1, entries 18-21). Pyrimidine N-oxide is less suitable, resulting in 20% yield when employing Conditions B and a 10% CuCN additive (Table 2.1, entry 17).³⁸d Quinoline (Table 2.1, entry 23) and isoquinoline (Table 2.1, entry 24) substrates are also suitable for the arylation.

*Conditions A: N-Oxide (2 eq), Triflate (1 eq), Pd(OAc)₂ (0.05 eq), HP(Cy₃)BF₄ (0.10 eq), Rb₂CO₃ (2 eq), PivOH (0.4 eq), PhMe (0.15 M), 100° C, 15 hrs. Conditions B: N-Oxide (2 eq), Triflate (1 eq), Pd(OAc)₂ (0.05 eq), HP(Bu₂)MeBF₄ (0.10 eq), K₂CO₃ (2 eq), PivOH (0.3 eq), PhMe (0.5 M), 110° C, 15 hrs. Isolated yields. Using 1.0 equivalents of N-Oxide. Using 1.5 equivalents of N-Oxide. Using 2.5 equivalents of N-Oxide. 10 mol % CuCN added. Using 1.1 equivalents of N-Oxide.
The more active nature of Conditions B compared to Conditions A is illustrated by two examples. Pyridazine N-oxide, which may undergo reaction at only one position, is arylated in 51% yield under Conditions A (Table 2.1, entry 14), but the yield increases to 99% when using Conditions B (Table 2.1, entry 15). Also, quinoline N-oxide is arylated in 68% yield under Conditions A (Table 2.1, entry 22) but in 81% yield under Conditions B (Table 2.1, entry 23). High yields can be obtained even when using 1 equivalent of N-oxide by utilizing Conditions B in conjunction with an N-oxide substrate where diarylation is not problematic as exemplified by the arylation of phthalazine N-oxide (Table 2.1, entry 26).

The arylation proceeds with a range of aryl triflates. Electron deficient aryl triflates result in somewhat diminished yields (Table 2.1, entries 5 and 21). Sterically demanding aryl triflates undergo reaction in 59 to 75% yield (Table 2.1, entries 7, 11, and 20); however, lower yields are obtained when used in combination with a sterically demanding N-oxide (Table 2.1, entry 25). Heterocyclic aryl triflates can also be employed as illustrated by the use of 3-pyridyl trifluoromethanesulfonate (Table 2.1, entry 21).

Differentially diarylated products can be obtained by carrying out the arylation reactions in sequence as shown in Scheme 2.6. Pyridine N-oxide is arylated with p-tolyl trifluoromethanesulfonate in 89% yield under Conditions A. This product can then be resubmitted to arylation conditions with 4-methoxyphenyl trifluoromethanesulfonate under the more active Conditions B to generate the differentially diarylated compound 2.4 in 84% yield. Previously reported conditions for the arylation of pyridine N-oxide with aryl bromides resulted in 50% yield of the desired product. These conditions also
require 4 equivalents of the $N$-oxide to obtain satisfactory yields. Conditions B, which employs aryl triflates, results in not only higher yield than the previously reported conditions but also requires less equivalents of intermediate $\text{2.3}$. Therefore it can be advantageous to employ aryl triflates when low yields are obtained with aryl bromides or when $N$-oxide substrates are precious.

![Scheme 2.6 – Differential Di-arylation](image)

To further investigate the reactivity and selectivity for reaction with aryl triflates, the arylation was carried out on a series of 3-substituted azine $N$-oxides (Table 2.2), affording a mixture of 2, 6 and disubstituted products. Alkyl substitution favors arylation at the 2-position, but diarylation is a significant by-product (Table 2.2, entries 1-2). Electron donating groups give more favorable selectivities for the 2-position and diarylation is not as problematic (Table 2.2, entries 3-4). Electron withdrawing substituents are the most selective substituents for the 2-position as only trace amounts of the 6-arylated product are observed (Table 2.2, entries 6 and 7). The only substitution that results in preferential arylation at the 6-position is a diethylamide substituent, which gives the 6-arylated product as the major regioisomer, which is possibly due to the increased steric requirements of this group (Table 2.2, entry 5).

The methodology for the direct arylation of azine N-oxides using aryl triflates was also evaluated in the context of the synthesis of key intermediate 2.8 for the synthesis of diarylpyridine 2.5,<sup>41</sup> which exhibits both antimalarial<sup>41</sup> and antimicrobial<sup>42</sup> activity. A

<sup>40</sup>This work was carried out by graduate student Christopher Whipp.
previous synthesis of 2,8, shown in Scheme 2.7, involves the assembly of the pyridine core with aryl groups already attached. We envisioned that, given that 2,8 is symmetrically bis-arylated, the greater propensity of aryl triflates to undergo bis-arylation compared to aryl halides may be capitalized upon. Consequently, methyl isonicotinate N-

![Scheme 2.7 – Formal Synthesis of 2.5](image)

oxide was subjected to Conditions B with two equivalents of 4-(trifluoromethyl)phenyl trifluoromethanesulfonate to yield 76% of the bis-arylated product 2.7. Compound 2.7 was then subsequently reduced and saponified to give 2.8 in 73% yield over two steps. Compared to the previous synthesis of 2.7, the direct arylation approach saves several chemical steps and is more amenable to the synthesis of derivatives.

2.3 Conclusions

In conclusion, a method was developed for the arylation of azine N-oxides with aryl triflates. The reaction is broadly applicable to a wide range of both azine N-oxides and aryl triflates. The arylation can be carried out in sequence to afford diarylated products. The method was applied to the formal synthesis of a medicinally relevant compound.
Direct Arylation as a Synthetic Tool for the Synthesis of Thiophene-based Organic Electronic Materials

3.1 Introduction

Organic materials have been studied intensively in recent years and are making significant contributions to the fields of light-emitting diodes, field-effect transistors, and photovoltaics among others. However, as these technologies become commercialized, the active compounds will be required in larger quantities. Therefore, developing efficient syntheses of these compounds is of paramount importance. State of the art syntheses usually rely on traditional cross-coupling reactions (Suzuki, Stille, Negishi, Kumada etc.). However, as mentioned in chapter 1, these methods have several drawbacks due to the use an organometallic reagent which generates a stoichiometric...
amount of metal waste. Moreover, these reagents are often toxic, difficult to handle, expensive or require extra synthetic steps to make. Recently, direct arylation has emerged as a viable alternative to traditional cross coupling, wherein the organometallic component is replaced with a simple arene (Scheme 3.1).

Scheme 3.1 – Synthesis of Thiophene Organic Materials

Ohta and coworkers made pioneering contributions over two decades ago reporting the first direct arylation of thiophenes with aryl halides via C-H bond functionalization using palladium catalysis at elevated temperatures (150 °C) and moderate yields.\(^{49a}\) Lemaire et

---

al. have also described thiophene direct arylation under phase transfer conditions which proceeded at 80 °C and with improved yields. Additionally, Doucet has reported thiophene arylation conditions that employ low catalyst loadings while being performed at 150 °C. While the mechanism of the C-H bond cleavage step in direct arylation has been debated, several research groups, including our own, have provided evidence for the concerted metalation deprotonation pathway. This mechanistic understanding lead to the development of pivalate as a proton shuttle/internal base additive which we have found gives superior reactivity under our reported conditions.

While direct arylation should be widely applicable, there is a paucity of examples of its utilization for the construction of organic materials. Takita and Ozawa have disclosed the use of palladium-catalyzed direct arylation for the synthesis of poly(3-alkylthiophene)s, which represents one of the most promising classes of π-conjugated

![Scheme 3.2 – Synthesis of Organic Materials Using Direct Arylation](image)

Mori has reported the synthesis of donor-acceptor type π-conjugated materials using direct arylation (Scheme 3.2).

In this chapter, we report the application of the direct arylation method to the (formal) synthesis of broad range of thiophene-based molecules which have exhibited promise for

---

Figure 3.1 – Thiophene Based Organic Materials

---

applications as optoelectronic materials (Figure 3.1). These syntheses require less synthetic operations than previously reported syntheses, are high yielding and avoid the use of organometallic reagents.

In the course of a research program dedicated to the development of direct arylation reactions, we became interested in organic electronic materials based on the thiophene moiety because they represent an important class of materials. In addition, thiophenes are ideal substrates for direct arylation due to the facile palladation through a CMD pathway which renders the reaction generally highly selective for the 2/5-position on thiophenes. We surmised that the application of the direct arylation reaction to the synthesis of known organic electronic molecules would result in shorter syntheses, and therefore higher yields, while avoiding organometallic intermediates and superfluous waste.

3.2 Results and Discussion

Park and co-workers have reported compound 3.1 for application in organic dye sensitized solar cells. In a previous report, 3.1 was synthesized from key intermediate 3.11 which was produced in 89% yield from a Suzuki coupling of 4-ethoxyphenylboronic acid with 5-bromo-2-thiophenecarboxaldehyde (Scheme 3.3). Using direct arylation, the boronic acid and aryl bromide could be replaced with an aryl bromide and a simple arene respectively. This would provide a more direct route using simpler and cheaper starting materials. Gratifyingly, the direct arylation proceeds using catalytic Pd(OAc)$_2$/PCy$_3$ with

30 mol% pivalic acid and K₂CO₃ in PhMe at 110 °C for 16 hours to give key intermediate 3.11. To demonstrate synthetic utility, this reaction was carried out on gram scale to afford 3.11 in quantitative yield, highlighting the excellent selectivity of the reaction. Another advantage of this synthesis is that it does not require chromatographic purification which becomes less practical as the scale of the reaction is increased.

The effectiveness of star shaped molecule 3.2 as a donor material in heterojunction solar cells has been shown by Roncali, Leriche and co-workers. The star-shaped molecule 3.2 was prepared from key intermediate 3.12 which was assembled in 77% overall yield via the Stille coupling of 2-(tributylstannyl)thiophene with tris(4-bromophenyl)amine followed by a Vilsmeier-Haack formylation (Scheme 3.4). Application of a direct arylation protocol gives 3.12 in one step and 89% yield using the same aryl bromide and 2-thiophenecarboxaldehyde in place of 2-(tributylstannyl)thiophene.

Scheme 3.3 – Formal Synthesis of 3.1

The Swager group has reported the use of compound 3.3 as a fluorescent marker for \textit{in vivo} optical imaging.\textsuperscript{59} The synthesis of 3.3 proceeds with the deprotonation of 2,2'-bithiophene followed by quench with \text{ClSn}(n\text{Bu})\textsubscript{3} to install the requisite stannane for the

\begin{scheme}
\textbf{Scheme 3.4 – Formal Synthesis of 3.2}

\end{scheme}

\begin{scheme}
\textbf{Scheme 3.5 – Formal Synthesis of 3.3}

\end{scheme}
subsequent Stille coupling which proceeds to give key intermediate 3.13 in 39% overall yield (Scheme 3.5). Alternatively, 3.13 can be prepared in one step from 2,2'-bithiophene using direct arylation under similar conditions as described above in 52% yield while avoiding organotin intermediates.

Hagfeldt and Sun described the application of 3.4 and 3.5 as chromophores for dye sensitized solar cells. Both were synthesized through common intermediate 3.15, which was prepared in 75% yield via a Suzuki reaction using 10 mol% catalyst (Scheme 3.6). The direct arylation route to 3.15 proceeds in 91% yield at 2 mol% catalyst loading and allows 5-formylthiophene-2-boronic acid to be replaced with the cheaper 2-thiophenecarboxaldehyde.

![Scheme 3.6 – Formal Synthesis of 3.4 and 3.5](image)

Marks has pioneered the use of 6 in organic field-effect transistors. Bithiophene 3.6 was constructed via the functionalization of 2,2'-bithiophene to the appropriate bisstannane followed by the Stille coupling with 3.16 to afford 3.6 in 60% overall yield.

---

(Scheme 3.7). Conversely, 3.6 can be made in one step and 87% yield from commercially available starting materials using direct arylation while avoiding organometallic intermediates.

![Scheme 3.7 – Synthesis of 3.6](image)

Cheng et al. have reported 3.7 as a liquid crystalline material. Their synthesis began with a Suzuki coupling with 2,5-dibromothiophene followed by a cyanation reaction using CuCN to give key intermediate 3.17 in two steps and 44% yield (Scheme 3.8). Using the direct arylation protocol 3.17 was synthesized in a single step and 97% yield using lower palladium loading and cheaper starting materials.

![Scheme 3.8 – Formal Synthesis of 3.7](image)

---

The group of Yang has described 3.8 as a soluble low band gap conducting polymer. The monomer 3.19 was assembled via a Kumada coupling in 46% yield (Scheme 3.9). By employing direct arylation, the Grignard reagent, which must be preformed and can be difficult to handle, can be replaced with an excess of simple thiophene to afford the same product in 66% yield.

**Scheme 3.9 – Formal Synthesis of 3.8**

Bo, Zhang and co-workers have shown that benzothiadiazole-based molecules such as 3.9 can be employed in efficient bulk heterojunction solar cells. 3.9 can be prepared from 3.20 which was synthesized via a Suzuki coupling between 2-thiopheneboronic acid pinacol ester and 3.14 in 51% yield (Scheme 3.10). Conversely, 3.20 can also be prepared in 86% yield by employing the same aryl bromide and using an excess of thiophene in place of 2-thiopheneboronic acid pinacol ester.

---

63 (a) Zhang, Q.; Li, Y.; Yang, M. *J. Mater. Sci.* 2004, 39, 6089. (b) Yang, M.; Zhang, Q.; Wu, P.; Ye, H.; Liu, X. *Polymer* 2005, 46, 6266.

Marks has also demonstrated perfluorobenzene substituted oligothiophenes such as 3.10 for use as n-type organic semiconductors.\textsuperscript{65} 3.10 was synthesized from 3.21 which had been prepared in 81\% yield using a Stille coupling between 2-(tributylstanny)thiophene and bromopentafluorobenzene (Scheme 3.11). Using direct arylation, organotin compounds can be avoided and 3.21 can be obtained in 86\% yield using 2-bromothiophene and pentafluorobenzene. This example demonstrates that in cases where both arenes have been shown to undergo direct arylation, such as with

\begin{align*}
\textbf{Scheme 3.10} & \quad \text{– Formal Synthesis of 3.9} \\
\end{align*}

\begin{align*}
\end{align*}
thiophenes\textsuperscript{49} and pentfluorobenzene,\textsuperscript{66,49u} it is possible to switch the bromine substitution such that bromothiophenes and a simple arene are utilized as coupling partners.

The direct arylation method is not without limitations. In the formal synthesis of 3.1, 3.2, 3.4, 3.5 and 3.7, two equivalents of the thiophene coupling partner per aryl bromide are required to achieve desirable product yields. However, the use of this excess is mitigated because it is readily available and relatively inexpensive. Additionally, it can be recovered from the reaction mixture by distillation if desired.

It is worth noting that under the conditions reported here, arylation always occurs selectively at the 2/5-position on thiophene\textsuperscript{67} with no byproducts arising from arylation of other positions detectable by spectroscopic methods. However, in cases where there are two possible reactive sites, as with thiophene and 2,2'-bithiophene, after arylation of one position the second position becomes more reactive towards direct arylation.\textsuperscript{68} This renders diarylation a significant reaction product. This is disadvantageous for the formal synthesis of 3.3, 3.8, and 3.9 in which only one arylation is desired. In those cases five equivalents of thiophene coupling partner are required to avoid diarylation and gives 3.13 and 3.20 in 52\% and 86\% yield respectively. Also, six equivalents are required to isolate 3.19 in 66\% yield. Again, the use of excess thiophene is mitigated because it is

\textsuperscript{68} Lapointe, D.; Gorelsky, S. I.; Fagnou, K. \textit{Unpublished Results}. 
inexpensive,\textsuperscript{69} easily handled and less toxic compared to organometallic coupling partners. As recently demonstrated in our group, one potential solution to this problem would be to employ a chlorine atom as an activating/blocking group.\textsuperscript{49t} Conversely, the tendency to undergo diarylation can also be advantageous if diarylation is desired, such as with 3.6. The ideal mol ratio of 2:1 aryl bromide to 2,2'-bithiophene can be employed to give 3.6 in 87% yield.

3.3 Conclusion

In conclusion, we have demonstrated the viability of direct arylation for the (formal) synthesis of a broad range of thiophene based organic electronic materials. Direct arylation has several advantages to traditional cross-coupling methods currently used for the construction of organic electronic materials and should be added to the “synthetic toolbox” of organic materials chemists. Direct arylation should be useful for the rapid and atom economical synthesis of an ever growing quantity of organic electronic materials, as well as streamline the synthesis of new thiophene-based organic electronic materials.

\textsuperscript{69} Thiophene is \$10/mol, whereas 2-(tributylstannyl)thiophene is \$1702/mol and 2-thienylboronic acid is \$2323/mol (base on prices as of April 30, 2011 from Sigma-Aldrich).
Site Selective Site-Selective $sp^2$ and $sp^3$ Direct Arylation of Azine N-oxides

4.1 Introduction

While rare even just a decade ago, direct arylation of heterocycles has become a valuable tool in the transformation of otherwise chemically inert C-H bonds into a number of functional groups. A particularly appealing and frequently discussed aspect of this chemistry involves the ubiquity of the C-H bond as a “functional group” and the potential to strategically transform these with high site selectivity. In practice, the challenge associated with achieving a high yielding reaction at even just one position makes the realization of controlled multi-site selectivity rare. Important advances have

---

70 A significant portion of the work described in this chapter has been published in the forms of a communication and a full article, see: (a) Campeau, L.-C.; Schipper, D.; Fagnou, K. J. Am. Chem. Soc. 2008, 130, 3266. (b) Schipper, D. J.; Campeau, L.-C.; Fagnou, K. Tetrahedron 2009, 65, 3155.

been made with some classes of electron-rich heteroaromatics (Scheme 4.1). For example, the inherent bias of azoles to undergo C5 direct arylation can be overridden through the use of copper additives which induce reaction at C2. 3-Carboxy furan and thiophene can be selectively arylated at either the C2 or C5 position. Sames has also

---

reported examples of C2/C3 site selectivity in indole arylations. Gaunt has demonstrated that regiocontrol can be achieved in indole and pyrrole alkenylation and arylation reactions through the choice of the solvent and theazole N-substituent. We have recently demonstrated that the choice of oxidant as well as the nature of the N-acyl substituent can reverse the site selectivity of the oxidative coupling of benzene with indole. Significantly, these reactions all involve selectivity at aromatic \( sp^2 \) C-H bonds.

In contrast to direct arylation at \( sp^2 \) centers, which has received much attention in recent years, direct arylation at \( sp^3 \) centers has received much less. This is likely due to the inherent difficulty in cleaving an \( sp^3 \) C-H bond. However, recently several reports of palladium catalyzed direct arylation at an \( sp^3 \) center have appeared. The first examples involved reaction of activated C-H bonds such as those \( \alpha \) to carbonyl groups. In 1997 the groups of Buchwald, Hartwig and Miura independently reported the \( \alpha \)-arylation of ketones (equation 4.1). Since that time this method has been expanded to include many other types of carbonyl functionalities.

---

In addition to the examples of intramolecular arylation of unactivated $sp^3$ C-H bonds,\(^{83}\) there have also been several recent reports on the intramolecular and intermolecular direct arylation of benzylic $sp^3$ C-H bonds (Scheme 4.2). Ren and Knochel have described the intramolecular direct arylation of benzylic pyrrole derivatives to form N–heterocycles.\(^{84}\) Hu and co-workers reported a tandem Kumada coupling/direct arylation which proceeded through benzylic C-H bond functionalization.\(^{85}\) The group of Sanford has achieved the chelation assisted arylation of a benzylic position using diaryliodonium salts.\(^{86}\)

**Scheme 4.2 – Benzylic Direct Arylations**

Of greater relevance to the chemistry presented in this chapter is direct arylation of azaaryl benzylic derivatives; of which there are several examples (Scheme 4.3). Yorimitsu and Oshima demonstrated the palladium-catalyzed direct arylation of aryl(azaaryl)methanes.\(^{87}\) Morris and Burton recently reported the benzylic arylation of 2-methylazaarenes.\(^{88}\) Concurrently with our work Charette and co-workers published on the arylation of 2-methyl \(N\)-iminopyridinium ylides.\(^{89}\) Importantly, no products arising from \(sp^2\) arylation are detected under these conditions.

**Scheme 4.3 – Direct Arylation of Azaaryl Benzylic Derivatives**

As a greater appreciation of the possible mechanisms of C-H bond cleavage/functionalization is gained, and particularly as transformations and mechanisms which exhibit complimentary and orthogonal reactivity are discovered, this long-term goal of chemo- and site selective direct functionalization should become increasingly achievable. Described in this chapter is: (1) operationally simple catalyst systems for the site selective direct arylation of \(sp^2\) and \(sp^3\) carbons of azine \(N\)-oxide substrates and several new examples, exhibiting broad scope for aryl chlorides, bromides, and iodides;

Scheme 4.4 – Catalyst controlled site selective $sp^2/sp^3$ arylation.

(2) that the arylation reactions can be carried out in either a divergent manner or a sequential manner in which either the $sp^2$ or the $sp^3$ arylation can be carried out first; (3) the application of the novel $sp^3$ arylation process to the synthesis of the natural products, Papaverine and Crykonisine, in three steps from simple starting materials; (4) insight into catalyst poisoning with electron deficient aryl halides leading to new mechanistic insights; (5) mechanistic studies pointing towards the intimate involvement of the base in the mechanism of the reactions.

4.2 Results and Discussion

Our group has described the use of $N$-oxides in direct arylation reactions as a means of avoiding the use of problematic organometallics in the formation of biaryl molecules.\(^\text{90}\) Ongoing studies revealed that lower yields were encountered with substrates bearing methyl substituents adjacent to the $N$-oxide moiety (Scheme 4.5). This prompted a re-evaluation of the $sp^2$ arylation conditions during which superior yields and selectivities were observed when using a 1:1 Pd(OAc)$_2$ to P$^\text{t}$Bu$_3$ stoichiometry compared to a 1:3 ratio (Table 4.1, entries 1 and 2). Pertinent to the chemistry that follows, the selection of the

Scheme 4.5 – Compared Reactivity of Pyridine N-oxide to Picoline N-oxide

base is crucial, with carbonates providing the optimal outcomes. Under these conditions, no other products are detected in $^1$H NMR analysis of the crude reaction mixture. High yields of the azine/diazone biaryl compounds can also be achieved as illustrated by Table 4.4.

The challenges associated with these substrates lead us to question whether competing palladacycle formation (such as 4.1) might be responsible for the challenging reactivity.$^{91}$ A corollary to this hypothesis is that intermediates such as 4.1 might also enable $sp^3$ arylation under appropriate conditions. Towards this goal, every aspect of the reaction was reinvestigated. A promising lead involved the combination of 4.3 with 1.5 equivalents of 4.2, 2.5 mol% Pd$_2$(dba)$_3$, 6 mol% S-Phos and 1.05 equivalents of NaO$t$Bu in toluene at 70 °C which provides 31% conversion to a 4.3:1 mixture of 4.5 and 4.6 (Table 4.1, entry 3).

$^{91}$ Reaction of 4-Picoline N-oxide under Conditions B yields only $sp^3$ arylation

**Conditions:** Substrates, Pd, ligand and base dissolved in PhMe and heated in an oil bath or microwave reactor. $^1$H NMR yield of the major product. $^b$ Isolated yield of the major product. $^c$ Using 1 mol% Pd.

While increasing the amount of $N$-oxide improves selectivity (entry 4), we also found that use of three equivalents of NaOrBu could also increase conversion and selectivity for 4.5 with two equivalents of $N$-oxide (entry 5). A survey of other ligands revealed that X-Phos provides 4.5 as the only product, albeit with only 41% conversion (entry 6). We were gratified to find that employing X-Phos and microwave heating at 110 ºC provides an 89% isolated yield of 4.5 with no drop in selectivity (entry 8). With these conditions, 1 mol% palladium and 1.5 equivalents of 4.2 can be used to provide an 84% isolated yield of 4.5 (entry 9). Importantly, no products arising from arylation at the $sp^2$ position are detected by $^1$H NMR analysis of the crude reaction mixture, indicating that a complete inversion in catalyst selectivity can be achieved.
4.2.1 Reaction Scope

A scope of the $sp^3$ arylation reaction with respect to the aryl halides is outlined in Table 4.2. Different aryl halides are tolerated including cheap and readily available chlorides (Table 4.2, entries 1, 10 and 12) as well as more commonly used bromides (Table 4.2, entries 2-5, 7-9, 11 and 13-14 and Table 4.3 entries 1-7) and iodides (Table 4.2, 1 entry 6). Arylation can be carried out using catalyst loadings as low as 1 mol % Pd (Table 4.2, entry 3). Also near equimolar amounts of the N-oxide and aryl halide can be employed (Table 4.2, entry 4). Thermal heating conditions were also developed utilizing Ru-Phos as the ligand although this method resulted in slightly diminished yields (Table 4.2, entry 5 and Table 4.3 entry 3).

A variety of substitution patterns including ortho, meta and para are tolerated on the aryl halide (Table 4.2). Very sterically demanding substrates require the use of S-Phos as the ligand (Table 4.2, entries 10 and 11). While electron-rich aryl halides are broadly applicable (Table 4.2, entry 13 and Table 4.3, entry 1), electron-poor aryl halides are not compatible with this catalyst system (Table 4.2, entry 15). Heterocyclic aryl halides can also be employed as illustrated by the use an indole halide (Table 4.2, entry 12).

We have determined that a broad range of N-oxide substrates can be used in $sp^3$ arylation reactions (Table 4.3). Meta and para methyl substituted aryl bromides participate in high yield and complete selectivity (Table 4.3, entries 1-3). Quinoline (Table 4.3, entry 4) and isoquinoline (Table 4.3, entry 5) N-oxides are also competent substrates, although 3 equivalents of 2-methylquinoline N-oxide must be used due to increased amounts of diarylation. Diazine N-oxides can be employed in the reaction as illustrated by the use of 2,3-dimethylidiazine N-oxide (Table 4.3, entry 6). Other alkyl

\(^a\)Conditions: N-oxide (2 eq.), Aryl Halide (1 eq.), Pd(OAc)\(_2\) (0.05 eq.), P\(_3\)Bu\(_3\)-HBF\(_4\) (0.06 eq.) and K\(_2\)CO\(_3\) (1.5 eq.) in PhMe (0.15 M), 110 °C, 16 h. \(^b\)Isolated yield. \(^c\)Using 0.15 eq. of P\(_3\)Bu\(_3\)-HBF\(_4\). \(^d\)Using 3 equiv. N-oxide. \(^o\)Using 1.1 equiv. N-oxide.
The scope of the $sp^2$ arylation of 2-methyl azine $N$-oxides is outlined in Table 4.4. The $sp^2$ arylation reaction is compatible with electron-neutral (Table 4.4, entries 1-6), electron-rich (Table 4.4, entries 7 and 9) and electron-poor (Table 4.4, entry 8) aryl bromides. A range of $N$-oxides, including substituted pyridines (Table 4.4, entries 1-4, 8 and 9), isoquinoline (Table 4.4, entry 6) and diazines (Table 4.4, entries 5 and 7) are suitable to be employed in the $sp^2$ arylation reaction.

To further demonstrate the utility of these methods for the functionalization of heterocycles, we have established that the $sp^2/sp^3$ arylations can be carried out in both a divergent and sequential manner (Scheme 4.6). Reaction of 2-picoline $N$-oxide (4.2) with bromotoluene was chosen as a model reaction. 2-Picoline $N$-oxide is arylated with 4-bromotoluene (4.3) under the $sp^2$ arylation conditions to give a 56% yield of product 4.4. $N$-oxide 4.4 is then subjected to the $sp^3$ arylation conditions with 2-bromotoluene to give a 77% yield of the differentially diarylated product 4.8. Alternatively, 4.2 could be first subjected to the $sp^3$ arylation conditions with 2-bromotoluene to give a 92% yield of product 4.7, demonstrating the divergent reactivity of a single substrate under different

![Scheme 4.6](image-url)
catalytic conditions. Compound 4.7 can then be arylated under the \( sp^2 \) conditions with 4-bromotoluene to give the same differentially diarylated product as the previous route in 59% yield.

The method for the \( sp^3 \) direct arylation of 2-methyl pyridine \( N \)-oxides was further validated in an efficient synthesis of natural products Papaverine (4.14) and Crykonisine (4.12) (Scheme 4.7). Papaverine is one of the four major components of opium and is used as a non-narcotic antispasmodic agent.\(^9^4\) Crykonisine is a natural product isolated

![Scheme 4.7 – Synthesis of Crykonisine and Papaverine.](image-url)

from the plant *Papaver Trinifolium* and the stem bark of *Cryptocarya Chinensis Hemsl.*\(^{95}\) To begin the syntheses compound 4.9 is oxidized to the N-oxide (4.10) by treatment with methyltrioxorhenium and aqueous hydrogen peroxide in CH\(_2\)Cl\(_2\).\(^{96}\) Compound 4.10 is then subjected to \(sp^3\) arylation conditions with 4-benzyloxybromobenzene which affords the arylated product 4.11. Simultaneous removal of the benzyl group and reduction of the N-oxide takes place under hydrogenation conditions with Pd/C in methanol to yield the natural product Cykonisine in 3 steps and 34% overall yield from commercially available starting materials. Papeverin can also be synthesized from the common intermediate 4.10, which is again subjected to \(sp^3\) arylation conditions with 4-bromoveratrole to yield 4.13. The N-oxide (4.13) is subsequently reduced with zinc in saturated NH\(_4\)Cl/THF to yield the natural product Papaverine in 3 steps and 30% overall yield.\(^{97}\) The syntheses of these two natural products from a common intermediate demonstrate the potential utility of this method for the generation of a large family of related compounds rapidly from common intermediates.

### 4.2.2 Limitations

halides, we hypothesized that the attenuated reactivity of electron-poor aryl halides might be explained by product inhibition of the catalyst. Upon arylation of the $sp^3$ position with an electron-deficient arene the benzylic protons become more acidic, which may lead to the formation of a stable palladacycle that is unable to participate in the reaction (Scheme 4.8). To test this hypothesis a poisoning experiment was carried out in which two reactions were performed; one without additive (Scheme 4.8, eq. 4.2) and one with 30 mol % 4.15 (Scheme 4.8, eq. 4.3). The reaction with no additive resulted in an 89% yield of the desired product, while the reaction with 30 mol % 4.15 added resulted in only 13% yield of the desired product. These results imply product inhibition may account for the diminished yields associated with electron deficient aryl halides.

4.2.3 Mechanistic Investigations

To investigate the role that C-H bond acidity at various sites plays in the site selectivity of these reactions, deuterium incorporation experiments were carried out (Scheme 4.9). Deuterium exchange of 2-picoline $N$-oxide by treatment with KOH in $D_2O$ reveals that
the methyl $sp^3$ site exchanges at a significantly faster rate than the $sp^2$ site adjacent to the nitrogen (eq. 4.4). Exchange on 2,4-lutidine N-oxide shows that the 2-methyl position undergoes exchange faster than the 4-methyl position and that the $sp^3$ position undergoes exchange at the slowest rate of the three positions (eq. 4.5). Exchange on 4-picoline N-oxide shows that in the absence of a 2-methyl substituent the 4-methyl position undergoes exchange faster than the $sp^2$ positions (eq. 4.6).

Scheme 4.9 – Deuterium Exchange Experiments

A series of experiments were also performed to determine if the N-oxide moiety influences regioselectivity (Scheme 4.10). Arylation of 2,4-lutidine N-oxide under the $sp^3$ arylation conditions results in exclusive reaction at the 2-methyl position (eq. 4.7). Arylation of 4-picoline N-oxide under the $sp^3$ arylation protocol results in exclusive arylation of the $sp^2$ center adjacent to the N-oxide (eq. 4.8). No product arising from arylation of the $sp^3$ center is observed (even though the $sp^2$ and $sp^3$ positions undergo deuterium exchange at a similar rate) (eq. 4.6). Given that arylation only occurs adjacent
to the N-oxide, it is plausible that N-oxide interactions with the palladium catalyst could play an important role in governing the selectivity of these reactions.

Scheme 4.10 – Effect of N-oxide Proximity on Regioselectivity

A series of experiments were also carried out to determine the role of the base in site selectivity (Table 4.5). Arylation of 2-picoline N-oxide with 4-bromotoluene under conditions similar to those used for \( sp^2 \) arylation (Condition A) using \( \text{K}_2\text{CO}_3 \) as the base yields 56% of the \( sp^2 \) arylated product with complete \( sp^2 \) selectivity (entry 1). Under identical conditions, but with \( \text{NaO}t\text{Bu} \) instead of \( \text{K}_2\text{CO}_3 \), a complete inversion of the \( sp^2/sp^3 \) selectivity is observed (entry 2). Similarly, under conditions analogous to those employed for \( sp^3 \) arylation (condition B) using \( \text{NaO}t\text{Bu} \) as the base, a 94% yield of \( sp^3 \) arylated product is obtained with complete selectivity for the \( sp^3 \) position (entry 3). Again if the base is changed under otherwise identical conditions from \( \text{NaO}t\text{Bu} \) to \( \text{K}_2\text{CO}_3 \), a complete inversion of the \( sp^2/sp^3 \) selectivity is observed (entry 4). These results indicate that it is the nature of the base that is of primary importance in determining \( sp^2/sp^3 \) site selectivity pointing towards its intimate involvement in the catalytic cycle.

*Condition A: 2-Picoline N-oxide (2 eq.), 4-bromotoluene (1 eq.), Pd(OAc)$_2$ (0.05 eq.), PBUHBF$_4$ (0.06 eq.) Base (1.5 eq.) in PhMe (0.15 M), 110 °C overnight. Condition B: 2-Picoline N-oxide (1.5 eq.), 4- bromotoluene (1 eq.), Pd$_2$dba$_3$ (0.025 eq.), X-Phos (0.05 eq.) Base (3 eq.) in PhMe (1 M), MW, 110 °C for 45 min. NMR Yield using 1,3,5-trimethoxybenezene as standard.

A catalytic cycle for these transformations is proposed in Scheme 4.11. The active Pd(0) catalyst oxidatively inserts into the aryl halide bond to generate intermediate 4.15. The next step, palladation of the N-oxide, determines site selectivity and is base dependant. With the strong base NaOttBu, the most acid $sp^3$ 2-methyl position may be deprotonated and proceeds through an intermediate similar to 4.21 to yield 4.17. This pathway would be analogous to the $\alpha$-arylation of carbonyls. Alternately, the deprotonation of the $sp^3$ C-H bond could occur intramolecularly through a palladium alkoxide intermediate 4.20. K₂CO₃ is not a strong enough base to deprotonate the 2-methyl position, but it does allow for the 6-membered transition state of a concerted metallation-deprotonation (CMD) pathway to activate the $sp^2$ position as depicted in Scheme 4.11, which gives rise to 4.16. We and others have evaluated this pathway for the C-H activation.

Scheme 4.11—Catalytic cycle for $sp^2/sp^3$ arylation.

of arenes. Both intermediates 4.16 and 4.17 then undergo reductive elimination to form products 4.18 and 4.19 respectively.

4.3 Conclusions

In conclusion, we have developed completely site selective arylation reactions on both $sp^2$ and $sp^3$ positions compatible with a broad range of azine $N$-oxides and aryl halides. The reactions are carried out in both a divergent and sequential manner. The efficacy of $sp^3$ arylation is demonstrated by the rapid synthesis of the natural products Papaverine and Crykonisine in three steps. Mechanistic studies reveal the importance of the nature of the base for catalyst controlled site selectivity. These reactions should find use for the rapid functionalization of azine derivatives and the mechanistic insights should lead to investigations of similar reactivity to other substrate classes.
Rhodium(III)-Catalyzed Intermolecular Hydroarylation of Alkynes

5.1 Introduction

Transition metal catalyzed direct transformations of aromatic C-H bonds is a burgeoning field in organic chemistry owing to its inherently efficient construction of organic building blocks. Of these processes, alkyne hydroarylation has received much attention in recent years because it allows for the atom economical synthesis of functionalized alkenes directly from simple arenes and alkynes. Hydroarylation of alkynes typically occurs by one of two pathways (Scheme 5.1). The first proceeds...
through activation of the alkyne by a cationic metal complex. The second proceeds via activation of the arene by oxidative insertion of a nucleophilic metal into a C-H bond. Although many intra- and intermolecular examples have been reported, these pathways have limited scope and utility since they usually necessitate the use of electron rich arenes, electron deficient alkynes or synthetically restricted directing groups. Moreover, the products are often obtained as regio- or stereoisomeric mixtures.

**Scheme 5.1 – Alkyne Hydroarylation Pathways**

Some recent examples of hydroarylation via Lewis acid activation of the alkyne are highlighted in Scheme 5.2. Fujiwara’s group has made seminal contributions to the field by describing palladium catalyzed intra and intermolecular hydroarylation of electron deficient alkynes. This hydroarylation was initially thought to proceed through arene metallation, but further mechanistic studies suggest the reaction proceeds

---

through a Friedel-Crafts-type reaction of a metal-activated alkyne. A recent report from Banwell and co-workers demonstrated that Au(I) is a competent catalyst for the intramolecular hydroarylation, resulting in a range of heterocycles. Also, Kitamura et al. have shown that the hydroarylation of propiolic acid with electron rich arenes provides a mixture of E/Z alkenes under iron(III) catalysis.

**Scheme 5.2** – Hydroarylation Via Alkyne Activation

Some recent examples of hydroarylation which proceed through oxidative insertion of a metal complex into a C-H bond are shown in Scheme 5.3. The regioselective hydroarylation of alkynes with aromatic ketones has been shown by Murai

---

and co-workers.\textsuperscript{109} Also, Lim and Kang have used rhodium catalysis to accomplish the 2-pyridyl directed hydroarylation of alkynes.\textsuperscript{110} In addition, the Hiyama group have demonstrated the competency of Ni(0) as a catalyst for the hydroheteroarylation of alkynes.\textsuperscript{111} Finally, the Rhenium-catalyzed hydroarylation has been reported by the Takai group.\textsuperscript{112}

\textbf{Scheme 5.3} – Arene Activation Via Oxidative Insertion

An alternative pathway is the activation of the arene with an electrophilic metal which could then undergo migratory insertion of the alkyne followed by protodemetalation (Scheme 5.1). Although this pathway holds promise to overcome

some of the limitations of hydroarylation, only Pd(II) catalysis has shown efficacy with two intramolecular examples (Scheme 5.4). In an elegant example Gevorgyan reported the hydroarylation of o-alkynyl biaryls.\textsuperscript{113} Under similar conditions Li has reported the hydroarylation of N-arylpropiolamides.\textsuperscript{114}

![Scheme 5.4 – Arene Activation Via Cationic Catalysis](image)

Although these examples represent important advancements, development of novel catalysts is still required to achieve elusive intermolecular reactivity. Described in this chapter is the Rh(III)-catalyzed intermolecular hydroarylation of alkynes. Mechanistic investigations suggest the reaction proceeds through arene activation by the cationic metal catalyst. This relatively unexplored pathway allows intermolecular hydroarylation to proceed in high yields for a range of arenes and internal alkynes and is highly regio- and stereoselective.

### 5.2 Results and Discussion

#### 5.2.1 Reaction Optimization

Our group, among others, has recently reported Rh(III) catalyzed transformations at aromatic C-H bonds. Because they are an important medicinal chemistry, the indole motif was selected along with Cp*Rh(MeCN)₃(SbF₆)₂ and 1-phenyl-1-propyne for reaction development. The choice of the protecting/directing group on indole was found to be crucial with N,N-dimethylcarbamoyl being optimal (Table 5.1). The increased reactivity of the N,N-dimethylcarbamoyl group is likely due to it increased basicity and therefore enhanced ability to direct a metalation event.

aConditions: Indole (1 equiv.), 1-phenyl-1-propyne (1.1 equiv.), Cp*Rh(MeCN)₃(SbF₆)₂ (5 mol%) and pivalic acid (5 equiv.) dissolved in tAmOH and heated at 100 °C for 15 hrs. bUsing 1,3,5-trimethoxy benzene as an internal standard.

The optimization of the reaction conditions are outlined in Table 5.2. We were pleased to find that heating the coupling partners in toluene with the catalyst afforded the

desired product, albeit without catalyst turnover (entry 1). Superior catalytic efficiency was obtained when 5 equivalents of acetic acid was added to the reaction (entry 2) and again upon the use of pivalic acid (entry 3). The use of the related non-cationic catalyst, \([\text{Cp}^*\text{RhCl}_2]\), lead to no reactivity in this reaction (entry 4). A screen of solvents revealed isopropylacetate to be superior to toluene (entry 5). Finally lowering the temperature to 90 °C gave 5.3a in near quantitative yield (entry 6).

### 5.2.2 Reaction Scope

Table 5.3 outlines the scope of the hydroarylation under our optimized reaction conditions. Both electron-donating (5.3b) and electron-withdrawing (5.3c,d) groups are tolerated on the indole, as is a chloro substituted substrate (5.3e). This catalyst system also allows for the use of other heterocycles (5.3f-h), a range of different types of directing groups (5.3h-k) as well as electron rich (5.3i,j) and electron poor (5.3k) simple substituted benzenes in hydroarylation. A range of alkynes are also compatible with the reaction including diaryl (5.3g,k), electron-rich arenes (5.3l), alkenyl (5.3m),

\(^{118}\) Use of the dimethylcarbamoyl protecting group in this case lead to poor conversion to product.
cyclopropyl (5.3n), heterocyclic (5.3o) trimethylsilyl (5.3p) as well as ester (5.3q) and protected alcohol (5.3r) moieties. The dimethyl carbamoyl group can be easily removed using KOH in EtOH/H₂O at 90 °C (Scheme 5.5).

Scheme 5.5 – Removal of Dimethyl Carbamoyl Group
5.2.3 Limitations

When indole is employed in the reaction, the scope with respect to the alkyne partner is limited. Dialkyl, diaryl and propiolate-type alkynes failed to give appreciable yields under our reaction conditions. We investigated if these alkynes were merely unreactive or if they were shutting down catalytic reactivity by conducting poisoning experiments (Table 5.4). With no additive hydroarylation of 5.2a with 5.1a gives 5.3a in 85% $^1$H NMR yield. However, in the presence of dialkyl, diaryl and propiolate-type alkynes the reaction yields are severely reduced.

$^a$Conditions: Indole (1 equiv.), alkyne (1.1 equiv.), additive (1.1 equiv.), $\text{Cp}^*\text{Rh(MeCN)}_3\text{(SbF}_6\text{)}_2$ (5 mol%) and acetic acid (5 equiv.) in iPrOAc (0.4 M) at 90 °C for 15 hrs. $^b$ $^1$H NMR yields.

Dialkyl and propiolate-type alkynes likely reduce catalytic activity by binding relatively strongly to the rhodium catalyst (Scheme 5.6). Rate inhibition by alkynes (especially dialkyl alkynes) in a similar catalytic system has been demonstrated by our group.$^{115b}$ Diaryl alkynes may undergo migratory insertion at increased rates allowing a second alkyne to do a migratory insertion. A subsequent cyclization/reductive
elimination step would afford an inactive Rh(I) species. This type of double alkyne addition has been demonstrated in similar catalytic systems.\textsuperscript{119}

![Scheme 5.6 – Reasoning for Catalyst Inhibition](image)

Terminal alkynes also failed to yield the desired product (Scheme 5.7). Instead, terminal alkyl alkynes gave only a regioisomeric mixture of alkyne trimerization products. Also, terminal aryl alkynes yielded only Markovnikov addition of pivalic acid to the alkyne. However, this problem can be avoided by employing silyl protected terminal alkynes (5.3p).

![Scheme 5.7 – Reactivity of Terminal Alkynes](image)

5.2.4 Mechanistic Investigations

In order to investigate the mechanism of the transformation, a series of deuterium incorporation experiment were performed. These experiments are outlined in Scheme 5.8. First, a background experiment was conducted which involved heating indole 5.1a in the presence of AcOD (eq. 5.1). No deuterium incorporation was observed in the absence of the catalyst which allowed us to conclude that any incorporation in subsequent reactions would be the result of a metalation/deuterodemetalation sequence. Therefore, deuterium incorporation can act as a “tracer” and observed incorporation would mean that the catalyst has spent time at that position. Another background experiment was conducted in which the reaction product 5.3a was heated at 90 °C in iPrOAc in with 5 mol% of the rhodium catalyst and 5 equivalents of AcOD for 3 hours (eq. 5.2). 69% Deuterium incorporation was observed at the C3 indole position which suggests reversible metalation at that position. More importantly, no deuterium incorporation was observed at the alkene position of the product, which established that any incorporation observed here would arise from a reaction intermediate and not from post-reaction incorporation.

A mechanism which involves a C-H oxidative insertion/reductive elimination sequence should not result in any incorporation at the alkene position (Scheme 5.1). To test this possibility, a reaction was conducted with AcOD in place of PivOH but taken only to 27% conversion with a 4 hour reaction time (eq. 5.3). 42% deuterium incorporation was observed at the alkene position of the product. However, a C-H bond oxidative insertion pathway could not be ruled out since 33% deuterium incorporation was also observed at the C2 indole position in the recovered starting material, which could conceivably explain incorporation at the alkene position.
Additionally, deuterium incorporation at the C3 and C7 indole positions in the recovered starting material may suggest that hydroarylation might take place at these positions; however, none of these products were observed. In order to definitively rule out the C-H bond oxidative insertion pathway the background deuterium incorporation at the indole C2 position would have to be reduced. This was accomplished by reducing the catalyst loading to 3 mol%, the reaction time to 1 hour and increasing the amount of alkyne used to 2 equivalents (eq. 5.4). In this case there is 54% deuterium

Scheme 5.8 – Deuterium Incorporation Experiments
incorporation at the alkene position and no deuterium incorporation at the C2 indole position. Additionally, C2-deuterated 5.1a was subjected to reaction conditions and deuterium incorporation was observed in the product (eq. 5.5). These results prove that the hydrogen at the alkene position of the product comes from the acid additive in the reaction and not from the substrate and rules out the possibility of a C-H bond oxidative insertion pathway.

The high selectivity for syn-addition renders the possibility of alkyne activation improbable (Scheme 5.1).\textsuperscript{103,120} However it is conceivable that syn-addition arises from isomerization of trans-addition product. A control experiment where a 1:2.2 mixture of E:Z isomers is exposed to the standard hydroarylation conditions shows no alkene isomerization (eq. 5.6), ruling out the possibility of alkene isomerization under reaction conditions or alkyne activation as the operative mechanistic pathway.

To gain insight into the nature of the C-H bond cleavage event, a competition between methoxyindole 5.1b and nitroindole 5.1c (eq. 5.7) which revealed a preference for the more electron rich arene (4:1 ratio). This outcome is consistent with results or related catalyst systems from our group\textsuperscript{121} and other groups\textsuperscript{122} in which the C-H bond

cleavage was determined to proceed though a concerted metalation-deprotonation type mechanism. However, an electrophilic rhodation mechanism cannot be ruled out.

A proposed catalytic cycle which would explain both the decrease in deuterium incorporation and the observed alkene geometry is shown in Scheme 5.9. First reversible directed metallation with the rhodium(III) catalyst occurs with concomitant loss of a proton. The alkyne can then coordinate to the rhodium center followed by migratory insertion. Finally protonolysis yields the product and regenerates the catalyst. An off-cycle fast and reversible metallation at the C-3 position of indole could explain the observed deuterium incorporation at that position.

Scheme 5.9 – Proposed Catalytic Cycle
5.3 Conclusions

In conclusion we have developed an intermolecular rhodium(III) catalyzed hydroarylation of alkynes. The reaction is applicable across a range of both arenes and alkynes. Consequently, this reaction should be useful for the rapid and atom economical preparation of organic building blocks. Furthermore, this novel reactivity for the intermolecular hydroarylation of alkynes should have broader implications for the development of related transformations.
Kinetic Resolution of β-Hydroxy Esters

6.1 Introduction

Despite remarkable advances in enantioselective synthesis, the preparation of single enantiomer quaternary stereocenters remains a challenging and important goal in organic chemistry. The difficulties associated with the use of ketone electrophiles are illustrative, where attenuated reactivity, challenging carbonyl enantiofacial differentiation and diminished stability towards retro-aldol decomposition can explain, in part, the wealth of techniques for enantioselective aldol additions to aldehydes compared to

---

123 A significant portion of the work described in this chapter has been published in the form of a communication, see: Schipper, D. J.; Rousseaux, S.; Fagnou, K. Angew. Chem. Int. Ed. 2009, 48, 8343.

ketones. In such instances, kinetic resolution of a racemic product may be an attractive alternative to enantioselective synthesis, which remains an important method of accessing enantiopure material.

While kinetic resolution of secondary alcohols has been studied extensively, there are few examples of tertiary alcohol resolutions (Scheme 6.1). In addition to enzymatic processes that have limited substrate scope, Miller has described a peptide based catalyst for the acylation of α-amino alcohols. Hoveyda and Snapper also used a peptide based catalyst for selective silylation of 1,2-diols including 3 examples of tertiary alcohols, as well as the desymmetrization of triols. Oestreich has shown that stereogenic silanes can be used to resolve chiral donor functionalized tertiary alcohols.

Matsunaga and Shibasaki also developed a resolution of tertiary nitroaldols through a retro-nitroaldol reaction catalyzed by mixed La-Li heterobimetallic complexes. Recently, Shintani and Hayashi reported a rhodium catalyzed resolution of tertiary homoallylic alcohols.

---

Described in this chapter is the unique reactivity/selectivity associated with (1S,2R)-N-methylephedrine in the resolution of tertiary alcohols arising from ketone aldol reactions. Even though the tertiary stereogenic center is three atoms removed from the reactive site, high selectivities are observed — with s-factors in excess of 20 in many instances. The method is technically simple to perform, and employs a cheap and readily available resolving agent (1S,2R)-N-methylephedrine (a chiral compound that is commonly used as a stoichiometric chiral auxiliary in diastereoselective carbon-carbon bond forming processes). Given the ease with which these racemic aldol processes may be performed, and the ease with which the products may be resolved, this chemistry

---

134 (1S,2R)-N-methylephedrine is available from Sh-Icon Inc. for ~$3/g.
should find application in the preparation of a wide array of natural and synthetic organic molecules.

6.2 Results and Discussion

The unique reactivity of \( N \)-methylephedrine was inadvertently discovered while evaluating the feasibility of amine catalyzed asymmetric decarboxylative ketone aldol reactions (Equation 6.1).\(^{136}\) While performing the addition of 6.1 to ethyl pyruvate in the presence of (1S,2R)-\( N \)-methylephedrine (6.2) as a chiral base, product was obtained with low yield but significant levels of enantiomeric excess when the reaction was allowed to proceed to completion over several days.\(^{137}\) Further analysis of the reaction, such as isolation of phenol as well as a transesterified product, indicated that the enantiomeric excess had arisen from a kinetic resolution of racemic product.

6.2.1 Reaction Optimization

\(^{137}\) This reaction was carried out by graduate student Sophie Rousseaux.
Following the initial discovery, a broad range of readily available chiral nucleophiles was evaluated for the kinetic resolution of 6.3 (Figure 6.1). With chiral alcohols such as 6.5 to 6.9, no reaction was observed at room temperature in the absence of other additives. In these cases, improved outcomes could be obtained by addition of one equivalent of triethylamine and heating to 60 °C (Table 6.1, entries 2-6). From these screens, (R)-(-)-pantolactone (6.7) (entry 4) and (1S,2R)-N-methylephedrine (6.2) (entry 14) provided promising s-factors of 3.7 and 3.5 respectively. While further optimization with 6.7 failed to produce superior results, continued evaluation of N-methylephedrine (6.2) revealed that by increasing the reaction temperature to 60 °C, the selectivity factor could be dramatically improved from 3.5 to 21 (entry 16). This can be further enhanced to a selectivity factor of 38 by using 2 equivalents of 6.2 (entry 17). The reaction progress occurs over several hours and may be monitored by HPLC over chiral support. Conveniently, the reaction may be performed in ACS grade toluene without necessitating the exclusion of air or moisture.

### 6.2.2 Reaction Scope

These optimized conditions were applied to a variety of compounds as illustrated in Table 6.2. In addition to 6.3, which may be isolated in 49% yield and 94/6 enantiomeric ratio (er), other tertiary alcohol compounds may be effectively resolved. A number of functionalities at the quaternary center may be present, including alkyl (Table 6.2, entries 1 and 5), aryl (Table 6.2, entries 2 and 4), ester (Table 6.2, entries 1-3), trifluoromethyl (Table 6.2, entries 3 and 4), and ketone (Table 6.2, entry 5) substituents. While optimized for tertiary alcohol compounds, this method may also be applied to aldehyde aldol products. Under standard conditions, the selectivity is lower with these
substrates. We were pleased to find, however, that the selectivity with secondary alcohols can be improved by modifying the aryloxy substituent of the ester. For example, by changing the leaving group from an oxy-ester (Table 6.2, entry 6) to a thio-ester (Table 6.2, entry 7), the $s$-factor is doubled from 8 to 16. Synthetically useful

selectivities are also attained with aliphatic aldehyde products (Table 6.2, entries 8 and 9). In contrast, low selectivities are obtained when the stereogenic center is directly adjacent to the reaction site (Table 6.2, entry 10).

Encouraged by the ability to modulate selectivity through modification of the leaving group (Table 6.2, entries 6 and 7), we also investigated this influence in reactions performed at room temperature employing only 0.6 equivalents of the resolving agent 6.2 (Table 6.3). Under these conditions, reaction of the unsubstituted phenol ester 6.3 results in only 10% conversion and an $s$-factor of 3.6 (Table 6.3, entry 1). Gratifyingly, this can be significantly improved through the use of a 4-cyano substituted aryl ester. In this case, 42% conversion is observed over the same time period and with an $s$-factor of 29.3 (Table 6.3, entry 3).

This chemistry may also be performed on larger scale (Equation 6.2). For example, treatment of one gram of 6.3 under the standard conditions results in the isolation of (+)-6.3 in 49% yield and 94/6 $er$. The other enantiomer of 6.3 can be isolated as the transesterified product (+)-6.26 as one major diastereomer (25/1 dr) in 43% yield along with 38% of unreacted 6.2. The overall yield of the reaction is 92% when
considering the recovery of both enantiomers. Moreover, the use of excess 6.2 is mitigated by its subsequent recovery from the reaction.

6.2.3 Mechanistic Insights

To gain mechanistic insights into the reactivity and high selectivity associated with the use of 6.2, a variety of experiments were carried out (Scheme 6.2). In these studies, a simplified system was employed by conducting the reaction with achiral 2-(dimethylamino)ethanol (6.27) instead of 6.2. To establish baseline reactivity, 3 was treated with 2 equivalents of 6.27 in toluene at 60 °C. After 12 hours, 64% conversion to ester 6.28 was obtained (Equation 6.3). In contrast, if the alcohol of 3 is protected as a tert-butyldimethylsilyl (TBS) ether, or if it is absent as in the case of phenylpropionate, no reaction is observed after the same reaction time (Equations 6.4 and 6.5). These results, in conjunction with the inferior outcomes associated with the use of α-
hydroxyesters (Table 6.2, entry 10), point to a key role of the β-hydroxyl moiety in establishing high reactivity and selectivity with these nucleophiles.

In a similar fashion, the role of the dimethylamine functionality of 6.2 and 6.27 on reactivity was evaluated. For example, no reaction is observed with benzyl alcohol as the nucleophile under standard conditions established for the resolution of 6.3 with 6.2 (Table 6.4, entry 1). Upon addition of one equivalent of triethylamine, up to 21% conversion is observed after 12 hours indicating that the base can accelerate the transesterification process (entry 2). When the amine base is attached to the alcohol nucleophile, as with 6.27, a further increase in conversion is observed (entry 3). When the more sterically encumbered 6.2 is employed, a drop in conversion is noted over the same reaction time (entry 4) and this conversion is not influenced by the addition of an

\(^a\) Conditions: Nucleophile, 6.2 and 1,3,5-trimethoxybenzene are dissolved in C\(_6\)D\(_6\) and allowed to stir at 60 °C for 12 hours. \(^b\) % conversion determined by measuring consumption of 6.3 by \(^1\)H NMR using 1,3,5-trimethoxybenzene as an internal standard.
extra equivalent of triethylamine to the reaction mixture (entry 5). These results indicate that the presence of base is a key element in enhancing the reactivity of the alcohol nucleophile through H-bonding interactions and that this property is enhanced when the alcohol and the amine are tethered as in 6.2 and 6.27.

A proposal for the origin of selectivity in these reactions is shown in Scheme 6.3. Since no reactivity is observed when the alcohol of the substrate is protected or removed (Scheme 6.2), H-bonding of the alcohol to the carbonyl of the phenyl ester may be a key element of electrophilic activation (Scheme 6.3). Conformational and NMR analysis of 6.2 support 6.2a as the predominant conformer in solution. A J_{H1-H2} coupling constant of 3.7 Hz that changes only slightly with heating or changing solvents indicates a gauche relationship, which is consistent with previous reports.\textsuperscript{138} Both conformations 6.2a and 6.2b should give rise to the same selectivity based upon the current analysis. Given the rate acceleration associated with 6.27 and 6.2 compared to the combined use of an alcohol nucleophile and an amine base, we propose that H-bonding of the substrate alcohol to the amine of 6.2 may be important for reactivity/selectivity. If nucleophilic attack of 6.2 on 6.29 or ent-6.29 occurs from the bottom face on stereoelectronic grounds, more severe steric interactions between the substituents of 6.29 and 6.2 should occur at 6.31 compared to reaction via 6.32. Under these circumstances, 6.29 remains unreacted but ent-6.29 undergoes transesterification to give 6.33.

6.3 Conclusions

In conclusion, we have developed a method for the kinetic resolution of tertiary alcohols arising from ketone aldol reactions and extended this reactivity to other aldol products. These reactions employ commercially available $(1S,2R)$-N-methylephedrine as the resolving agent and are technically simple to perform. Given the challenge associated with the generation of quaternary stereocenters, this methodology should contribute meaningfully to the repertoire of techniques available to chemists for the preparation of single enantiomer tertiary alcohols of this type.
Enantioselective Organocatalysis Using Simple Aldehydes Temporary Tethers

7.1 Introduction

The enzymes’ ability to promote preassociation is an important feature to rationalize their remarkable efficiency in catalyzing intermolecular reactions.\(^{139}\) In organic synthesis, the use of directing or tethering groups allowing preassociation with a reagent or catalyst is a common strategy to achieve temporary intramolecularity which often leads to increases in reactivity, rate, regio- and stereoselectivity of formally intermolecular reactions.\(^{140}\) Typically, such interaction involves hydrogen bonds, coordination to a metal catalyst or stepwise installation of a temporary tether.

While these methods have proven advantageous in many cases they suffer from a drawback of auxiliary-type approaches: additional steps are required for its formation and cleavage. Some tethering strategies are highlighted in Scheme 7.1. Craig has demonstrated the use of silicon based tethers to achieve challenging Diels-Alder

Also, Stork has made several contributions including silicon, magnesium and aluminum teathers for Diels-Alder reactions and radical cyclizations. Finally, Breslow has established the efficacy of a templated, biomimetic approach to functionalization of steroid derivatives including chlorination and dehydrogenation.

**Scheme 7.1 – Examples of Tethered Reactions**

Given the effectiveness and drawbacks of a tethering approach we envisioned an alternative strategy. This approach would involve the use of a simple organic molecule that could temporarily and catalytically covalently link to reactants allowing a formally intermolecular reaction to take place in an intramolecular fashion (Figure 7.1). We

---

reasoned that this strategy should increase reactions rates or allow for intermolecular reactivity that is otherwise impossible.

![Image of Figure 7.1 - Proposed Catalytic Tethering Strategy](image)

**Figure 7.1 – Proposed Catalytic Tethering Strategy**

A related strategy, which has received increased attention recently, is the catalytic and transient covalent attachment of a substrate, which is to undergo a transition metal mediated reaction, to the ligand, which is to bind to the metal (Scheme 7.2).\textsuperscript{144,145,146,147}

For example, the Bedford group has exploited the exchange of phenols on phosphinite-type ligands for the ortho-arylation of phenols.\textsuperscript{145} Also, Tan and co-workers have used a scaffolding ligand to achieve the selective, rhodium-catalyzed hydroformylation of

homoallylic alcohols. Breit and Grünanger have reported a similar strategy for the hydroformylation of bishomoallylic alcohols.

Scheme 7.2 – Scaffolding Ligands as a Strategy for Directing Reactions

---

Previous work from the Beauchemin group saw the development of Cope-type hydroaminations of alkenes and alkynes. While the intermolecular hydroamination of alkynes is broad in scope, the hydroarylation of alkenes is more challenging. In fact, intermolecular hydroaminations proceed only at elevated temperatures with strained and/or biased alkenes such as norbornene and styrene (Scheme 7.3, eq. 7.1 and 7.2). Interestingly, when the alkene and hydroxylamine are tethered (Scheme 7.3, eq. 7.3), the subsequent intramolecular hydroamination of the unbiased alkene proceeds at room temperature (Scheme 7.3, eq. 7.3). This reactivity highlights favourable reactivity obtained with intramolecular reactions when compared to related intermolecular reactions.

Scheme 7.3 – Cope-Type Hydroamination of Alkenes

---

Knight has also described some elegant work on the synthesis of 1,2,5-oxadiazinanes via addition of allyl amines to nitrones leading to the in situ generation of hydroxylamines as reaction intermediates (Scheme 7.3, eq. 7.4).\textsuperscript{149}

Building on this work it was hypothesized that the equivalent of an aldehyde tether in Knight’s system might be rendered catalytic under certain conditions. Therefore, the intermolecular Cope-type hydroamination of alkenes would be an ideal setting in which to investigate an organocatalytic tethering strategy.

\textbf{7.2 Results and Discussion}

\textbf{7.2.1 Reaction Discovery}

\(\alpha\)-Heteroatom substituted aldehydes are known to undergo facile hydrate formation because they are both kinetically and thermodynamically more reactive due to the inductive substituent (Scheme 7.4, eq. 7.5).\textsuperscript{150} This suggested that \(\alpha\)-heteroatom substituted aldehydes may be successful catalysts in related acetal/aminal based-tethering strategies. Indeed, upon extensive screening of aldehydes and other parameters, the reaction conditions shown in scheme 7.4, eq. 7.6 were developed.\textsuperscript{151} 2-(Benzyloxy)acetaldehyde proved to be the optimal catalyst for the hydroamination of allylamine with \textit{N}-benzylhydroxylamine.

\begin{itemize}
\item \textsuperscript{151} Reaction discovery was performed by graduate student Joseph Moran. Reaction optimization was performed by graduate students Peter Ng and Melissa Macdonald.
\end{itemize}

* Conditions: Hydroxyamine (1 equiv.), allylamine (1.5 equiv.), α-benzylloxyacetaldehyde (20 mol%) and solvent (1 mL) were charged to a vial and stirred at room temperature for 24 hours. * Isolated yield
and is shown in Table 7.1. The organocatalytic reaction is compatible with allyl amine (entry 1) as well as \(N\)-substituted allyl amines (entries 2-7). A range of hydroxylamines are also suitable substrates including benzyl (entries 1-4 and 6), substituted benzyl (entry 5) and aliphatic (entry 7) groups as substituents on the nitrogen atom.

### 7.2.3 Mechanistic Discussion

A proposed catalytic cycle is shown in Scheme 7.5. First, the condensation of the hydroxylamine onto the aldehyde forms a nitrone. Attack of the allylamine onto the nitrone leads to an aminal intermediate which can undergo a facile intramolecular Cope-type hydroamination. The resultant charged intermediate can undergo aminal cleavage to yield an iminium intermediate. Finally, condensation of a second molecule of hydroxylamine yields the product.

![Scheme 7.5 – Proposed Catalytic Cycle](image)

---

\(^{152}\) Reaction scope was performed by graduate students Peter Ng and Melissa Macdonald.
hydroxylamine completes the catalytic cycle and releases the product which is the result of a formal intermolecular hydroamination.

### 7.2.4 Enantioselectivity

One of the hallmarks of successful organocatalysis methods is the ability for the transformations in an enantioselective manner. Therefore, encouraged by the success of this novel temporary tethering strategy and the importance of the chiral 1,2-diamine motif,\textsuperscript{153} we sought validation in the context of enantioselective catalysis. Efforts began with the screening of commercially available or easily prepared chiral aldehydes with α-heteroatoms as catalysts for the intramolecular hydroamination of N-methylallylamine with N-benzylhydroxylamine (Scheme 7.6). A chiral aldehyde reported by the Ley group\textsuperscript{154} resulted in 71% isolated yield but racemic product. Garner’s aldehyde gave both

![Scheme 7.6 – Catalyst Screen for Enantioselective Hydroamination](image)

\textsuperscript{154} Michel, P.; Ley, S. V. \textit{Angew. Chem. Int. Ed.} \textbf{2002}, \textit{41}, 3898.
poor yield and enantioselectivity. However, D-glyceraldehyde acetonide gave the desired product in 91% isolated yield and 44% enantiomeric excess.

The enantioselective reaction can also be applied to other substrates as demonstrated by the reaction of N-benzylallylamine with N-benzylhydroxylamine (Scheme 7.7, eq 7.8). It is worth noting that the products of the hydroamination reactions are quite polar and not amenable to chiral HPLC analysis. Therefore a simple derivatization with carbodiimide is required to obtain compounds that can be analyzed by chiral HPLC. Additionally, the absolute stereoconfiguration was determined by optical rotation.\(^{155}\) Hydroamination of N-benzylallylamine with N-benzylhydroxylamine with D-glyceraldehyde acetonide, resulted in not only a superior yield to α-benzylxyacetaldehyde (62%) but also an enantiomeric excess of 74%, which represents the highest ee obtained for intermolecular hydroamination of unactivated alkenes by any method, including metal catalyzed reactions.\(^{156}\)

---

\(^{155}\) Determination of absolute stereochemistry was conducted by graduate student Melissa Macdonald.

An experiment was carried out to determine if the suboptimal ee’s obtained were due to catalyst epimerization under the reaction conditions. If this were the case one would expect the ee’s to be higher at lower conversion and decrease at higher conversions as more time is given for catalyst epimerization. Also, an increased catalyst loading would give enough product, at early conversions, to be characterized. However, hydroamination of N-methylallylamine with N-benzylhydroxylamine using 40 mol% D-glyceraldehyde acetonide as catalyst and 2.5 hour reaction time actually gave a lower ee value of 40% (eq 7.9) when compared to optimized reaction conditions (eq 7.7). These results demonstrate reduced ee’s are not likely the result of catalyst epimerization.

### 7.2.5 Dichloromethane as a Catalyst

In their open form simple aldose sugars, such as glucose, contain an α-oxyaldehyde. Therefore we considered that they may be operative organocatalysts for the Cope-type hydroamination of allylamines. Indeed, we were delighted to see that the employment of a range of simple sugars as catalyst in dichloromethane at room temperature for 16 hours gave NMR yields from 34-49% as the racemate (Scheme 7.8). A solvent screen revealed that dichloromethane to be the only suitable solvent with all other solvents tested (PhMe, MeOH, acetone, EtOAc, Et₂O, THF, CH₃CN, iPrOH, H₂O and CH₃NO₂) giving 0-7% NMR yield. Additionally, catalyst loading seemed to have little effect as 5, 10 or 20 mol% of glucose all gave between 73-76% yield over a 20 hour reaction time. Given the lack of enantioselectivity and effect from the type of sugar used
as the catalyst and the catalyst loading, we began to wonder if the sugar was acting as a catalyst at all. A control experiment confirmed that indeed the reaction proceeds at room temperature in the absence of catalyst to give 46% NMR yield (Scheme 7.9).

![Scheme 7.8 – Control Experiment](image)

We were curious about unique reactivity of dichloromethane compared to that of other solvents. One possible explanation is the nucleophilic displacement of the chlorines on dichloromethane with the amine or hydroxylamine to yield a formaldehyde equivalent. This formaldehyde equivalent could act then as a temporary tether similar to 2-(benzyloxy)acetaldehyde. To test this hypothesis a reaction carried in DMSO as a

![Scheme 7.9 – Dichloromethane Control Experiments](image)

---

158 These reactions were carried out by undergraduate Eric Bilodeau: Bilodeau, E. Honours Thesis, University of Ottawa, 2011.
solvent and gave only 8% yield of the product (Scheme 7.9). However when a catalytic amount of dichloromethane is added to the reaction mixture to product in produced in 75% NMR yield. This experiment confirmed that, while not responsible for all of the reactivity, CH$_2$Cl$_2$ was playing a unique and catalytic role.

The catalytic cycle for the proposed reaction is outlined in Scheme 7.10. First, the displacement of the chlorines on the dichloromethane precatalyst generate a nitron. Attack of the allylamine onto the nitron leads to an aminal intermediate which can undergo a facile intramolecular Cope-type hydroamination. The resultant charged intermediate can undergo aminal cleavage to yield an iminium intermediate. Finally, condensation of a second molecule of hydroxylamine completes the catalytic cycle and releases the product.

Scheme 7.10 – Proposed Dichloromethane Catalytic Cycle
7.3 Conclusion

In conclusion, we have reported the validation of organocatalytic tethering strategy to achieve challenging intermolecular reactions. The method’s potential for enantioslective reactivity has been demonstrated. Also, a unique and catalytic role for dichloromethane was uncovered. This approach represents a new paradigm in organocatalysis and we expect this advancement will prompt the investigation and development of a broad range transformations using this concept.
Supporting Information

8.1 General Methods

All palladium catalyzed direct arylation were carried out under Argon atmosphere. $^1$H, $^{13}$C, and DEPT-135 NMR spectra were recorded on a Bruker AVANCE 400 MHz, Bruker AVANCE 300 MHz or Varian INOVA 500 MHz spectrometers. Fourier-transform infra-red (FTIR) spectra were obtained as thin films on sodium chloride plates. High resolution mass spectra were obtained with a Kratos Concept IIH mass spectrometer. Melting points were recorded using a Gallenkamp Melting Point Apparatus and are reported uncorrected. All spectra of compounds completely characterized in this thesis are provided as electronic supporting information (attached CD). All other compounds have been reported in the literature or are commercially available.

8.2 Palladium-Catalyzed Direct Arylation with Aryl Triflates

General Triflation Procedures:

Transformation of Alcohols to Triflates: To a cooled (0 °C) biphasic mixture of toluene (30 mL), 30% (w/v) aqueous K$_3$PO$_4$ (30 mL), and the phenol (15 mmol, commercially available) was added dropwise Tf$_2$O (18 mmol) at a rate to maintain the reaction temperature <10 °C. The reaction was allowed to warm to ambient temperature and stirred for 30 min. The layers were separated, and the toluene layer was washed with water (30 mL) and extracted with EtOAc. The organics were combined, dried with anhydrous magnesium sulphate then concentrated in vacuo to give a liquid. The crude was subjected to flash chromatography to elute the corresponding triflate (15% Ether: 85% Pet Ether).

Transformation of Phenols with EWG to Triflates: To a stirred solution of para-trifluoromethyl phenol (1.0 g, 6.18 mmol) in anhydrous pyridine (3 cm$^3$) at 0° C was added trifluoromethanesulfonic anhydride (1.12 mL, 6.79 mmol) dropwise over 5 min.
The clear colourless solution changed to a dark orange colour and was allowed to return slowly to room temperature. After 48 h the reaction was quenched with water, extracted into CH₂Cl₂ (5 x 15 cm³) and the organic phase washed with 1 M hydrochloric acid (20 cm³), water (20 cm³) and brine (10 cm³). The organic phase was dried over anhydrous magnesium sulphate, filtered and the solvent removed in vacuo to give a pale yellow liquid. After purification by flash chromatography, eluting with 10% ethyl acetate in pet ether, para-trifluoromethylphenyl triflate (1.50 g, 74% yield) was obtained as a clear colourless liquid.

**General Direct Arylation Procedures:**

**Condition A:** Pd(OAc)₂ (5 mol%), PCy₃·HBF₄ (10 mol%), rubidium carbonate powder (Rb₂CO₃, 2 equiv.), pivalic acid solid (PivOH, 0.4 equiv.) and azine N-oxide (1.1-2 equiv.) are weighed to air and placed inside a Radley test tube. The tube is then flushed with Argon and capped with a rubber septum. The whole setup is then evacuated under vacuum and refilled with Argon five times. In a solution of Toluene (0.15M), the aryl triflate (1 equiv.) is then added under a steady flow of argon. After addition, the cap is sealed with parafilm wax and reaction is immersed in an oil bath. Stirring is commenced and the heating source is turned on (set to 100ºC). The reaction is left stirring for 12-18 hours (overnight), then allowed to cool, diluted with DCM and filtered over celite. The residues are then purified using silica gel chromatography.

**Condition B:** Pd(OAc)₂ (5 mol%), P⁴Bu²Me·HBF₄ (10 mol%), potassium carbonate powder (K₂CO₃, 2 equiv.), pivalic acid solid (PivOH, 0.3 equiv.) and azine N-oxide (1.1-2 equiv.) are weighed to air and placed inside a Radley test tube. The tube is then flushed with Argon and capped with a rubber septum. The whole setup is then evacuated under vacuum and refilled with Argon five times. In a solution of Toluene (0.5M), the aryl triflate (1 equiv.) is then added under a steady flow of argon. After addition, the cap is sealed with parafilm wax and reaction is immersed in an oil bath. Stirring is commenced and the heating source is turned on (set to 110ºC). The reaction is left stirring for 12-18 hours (overnight), then allowed to cool, diluted with DCM and filtered over celite. The residues are then purified using silica gel chromatography.

A solution of 4-(methoxycarbonyl)-2,6-bis(4-(trifluoromethyl)-phenyl)pyridine 1-oxide (148 mg, 0.335 mmol, 1 equiv) and zinc dust (99 mg, 1.509 mmol, 4.5 equiv) in THF:NH₄Cl satd 1:1 (3.5 ml) is stirred at room temperature overnight. The reaction is diluted with ether, dried over MgSO₄, and filtered over Celite. The crude product is purified by column chromatography (10–15% ether/pet. ether) to give a white solid in 87% yield.

**1H NMR (400MHz, CDCl₃, 293K, TMS):** 4.05 (3H, s), 7.79 (4H, d, J=8.2 Hz), 8.31 (4H, d, J=8.1 Hz), 8.34 (2H, s);

### 8.3 Direct Arylation as a Synthetic Tool for the Synthesis of Organic Electronic Materials

Scheme 3.3 (compound 3.11)

\[ \text{O} \quad \text{O} \quad \text{S} \quad \text{O} \]

K\(_2\)CO\(_3\) (1.5 equiv), Pd(OAc)\(_2\) (2 mol %), PCy\(_3\)-HBF\(_4\) (4 mol %), and PivOH (30 mol %) were weighed to air and placed in a 50 mL round bottomed pressure vessel equipped with a magnetic stir bar. The tube was purged with argon, and toluene (20 mL, 0.3 M), 2-thiophenecarboxaldehyde (2 equiv) and 1-bromo-4-ethoxybenzene (6 mmol) were then added. The reaction mixture was then vigorously stirred at 110 °C for 16 hours. The solution was then cooled to rt, diluted with CH\(_2\)Cl\(_2\) and H\(_2\)O. The aqueous phase was extracted with CH\(_2\)Cl\(_2\) (3X). The organics were combined and dried over MgSO\(_4\), filtered, and evaporated under reduced pressure. Excess 2-thiophenecarboxaldehyde was then removed using Kugelrohr distillation to give 3.11 in 99% yield (1.35 g). Spectral data corresponded to that previously described in the literature.\(^{164}\) Alternatively the reaction was also carried out in a similar manner to 3.15 and gave an 84% yield.

**\(^1\)H NMR (400MHz, CDCl\(_3\), 293K, TMS):** 1.44 (3H, t, J=7.0Hz), 4.08 (2H, q, J=7.0Hz), 6.94 (2H, d, J=8.9Hz), 7.29 (1H, J=4.0Hz), 7.60 (2H, d, J=8.9Hz), 7.71 (1H, d, J=4.0Hz), 9.86 (1H, s).

---

Scheme 3.4 (compound 3.12)

K₂CO₃ (1.5 equiv), Pd(OAc)₂ (6 mol %), PCy₃·HBF₄ (12 mol %), PivOH (30 mol %) and tris(4-bromophenyl)amine (0.3 mmol) were weighed to air and placed in a screw-capped vial equipped with a magnetic stir bar. The vial was purged with argon then toluene (1.3 mL) and 2-thiophenecarboxaldehyde (6 equiv) were then added. The reaction mixture was then vigorously stirred at 100 °C for 16 hours. The solution was then cooled to rt, diluted with CH₂Cl₂ and H₂O. The aqueous phase was extracted with CH₂Cl₂ (3X). The organics were combined and dried over MgSO₄, filtered, and evaporated under reduced pressure. The crude product was purified by silica gel column chromatography to afford 3.12 in 89% yield. Spectral data corresponded to that previously described in the literature.¹⁶⁵

¹H NMR (400MHz, CDCl₃, 293K, TMS): 7.19 (6H, d, J=8.7Hz), 7.36 (3H, d, J=4.0Hz), 7.61 (6H, d, J=8.7Hz), 7.74 (3H, d, J=4.0Hz), 9.89 (3H, s);

¹³C NMR (100MHz, CDCl₃, 293K, CHCl₃): 123.6, 124.6, 127.6, 128.4, 137.6, 142.0, 147.5, 153.6, 182.7.

Scheme 3.5 (compound 3.13)

K₂CO₃ (1.5 equiv), Pd(OAc)₂ (2 mol %), PCy₃·HBF₄ (4 mol %), PivOH (30 mol %) and 2,2'-bithiophene (5 equiv to avoid diarylation) were weighed to air and placed in a screw-capped vial equipped with a magnetic stir bar. The vial was purged with argon then toluene (1 mL, 0.3 M) and (4-bromophenoxy)(tert-butyl)dimethylsilane (0.3 mmol) were then added. The reaction mixture was then vigorously stirred at 100 °C for 16 hours. The solution was then cooled to rt, diluted with CH₂Cl₂ and H₂O. The aqueous phase was extracted with CH₂Cl₂ (3X). The organics were combined and dried over MgSO₄, filtered, and evaporated under reduced pressure. The crude product was purified by silica

\end{center}

K\textsubscript{2}CO\textsubscript{3} (1.5 equiv), Pd(OAc)\textsubscript{2} (2 mol \%), PCy\textsubscript{3}-HBF\textsubscript{4} (4 mol \%), PivOH (30 mol \%) and 4-bromo-N,N-diphenylaniline (0.5 mmol) were weighed to air and placed in a screw-capped vial equipped with a magnetic stir bar. The vial was purged with argon then toluene (1.7 mL, 0.3 M) and 2-thiophenecarboxaldehyde (2 equiv) were then added. The reaction mixture was then vigorously stirred at 100 °C for 16 hours. The solution was then cooled to rt, diluted with CH\textsubscript{2}Cl\textsubscript{2} and H\textsubscript{2}O. The aqueous phase was extracted with CH\textsubscript{2}Cl\textsubscript{2} (3X). The organics were combined and dried over MgSO\textsubscript{4}, filtered, and evaporated under reduced pressure. The crude product was purified by silica gel column chromatography to afford 3.15 in 91\% yield. Spectral data corresponded to that previously described in the literature.\textsuperscript{167}

\textbf{\textsuperscript{1}H NMR (400MHz, CDCl\textsubscript{3}, 293K, TMS)}: 7.03-7.16 (8H, m), 7.26-7.32 (5H, m), 7.51 (2H, d, J=8.8Hz), 7.70 (1H, d, J=4.0Hz), 9.85 (1H, s).

Scheme 3.7 (compound 3.6)

\begin{center}
\includegraphics[width=0.2\textwidth]{scheme3.7.png}
\end{center}

K\textsubscript{2}CO\textsubscript{3} (1.5 equiv), Pd(OAc)\textsubscript{2} (2 mol \%), PCy\textsubscript{3}-HBF\textsubscript{4} (4 mol \%), PivOH (30 mol \%) and 2,2'-bithiophene (0.3 mmol) were weighed to air and placed in a screw-capped vial equipped with a magnetic stir bar. The vial was purged with argon then dimethylacetamide (1 mL, 0.3 M) and 1-bromo-4-hexylbenzene (2 equiv) were then added. The reaction mixture was then vigorously stirred at 100 °C for 16 hours. The solution was then cooled to rt, diluted with CH\textsubscript{2}Cl\textsubscript{2} and H\textsubscript{2}O. The aqueous phase was extracted with CH\textsubscript{2}Cl\textsubscript{2} (3X). The organics were combined and dried over MgSO\textsubscript{4}, filtered, and evaporated under reduced pressure. The crude product was purified by silica gel column chromatography to afford 3.6 in 87\% yield. Spectral data corresponded to that previously described in the literature.\textsuperscript{168}

K₂CO₃ (1.5 equiv, 0.75 mmol, 103.7 mg), Pd(OAc)₂ (2 mol %, 0.01 mmol, 2.2 mg), PCy₃·HBF₄ (4 mol %, 0.02 mmol, 7.4 mg) and pivalic acid (30 mol %, 0.15 mmol, 15.3 mg) were weighed to air and placed in a screw-capped vial equipped with a magnetic stir bar. The vial was purged with argon then toluene (1.7 mL, 0.3 M), 2-thiophenecarbonitrile (2 equiv, 1 mmol, 93 µL) and 4-bromoanisole (1 equiv, 0.5 mmol, 62 µL) were then added. The reaction mixture was then vigorously stirred at 100 °C for 16 hours. The solution was then cooled to r.t., diluted with CH₂Cl₂ and H₂O. The aqueous phase was extracted with CH₂Cl₂ (3X). The organics were combined and dried over MgSO₄, filtered, and evaporated under reduced pressure. The crude product was purified by silica gel column chromatography to afford 17 in 97% yield (104.9 mg). Spectral data corresponded to that previously described in the literature.¹⁶⁹

¹H NMR (400MHz, CDCl₃, 293K, TMS): 3.85 (3H, s), 6.95 (2H, d, J=8.9Hz), 7.16 (1H, d, J=3.9Hz), 7.53 (2H, d, J=8.9Hz), 7.56 (1H, d, J=3.9Hz).

K₂CO₃ (1.5 equiv, 3 mmol, 414.6 mg), Pd(OAc)₂ (6 mol %, 0.12 mmol, 26.9 mg), PCy₃·HBF₄ (12 mol %, 0.24 mmol, 88.4 mg), pivalic acid (30 mol %, 0.6 mmol, 61.3 mg) and 4,4'-dibromobiphenyl (1 equiv, 2 mmol, 624.0 mg) were weighed to air and placed in a round bottomed pressure vessel equipped with a magnetic stir bar. The tube was purged with argon, and toluene (6.7 mL, 0.3 M) and thiophene (6 equiv, 12 mmol, 960 µL) were then added. The reaction mixture was then vigorously stirred at 110 °C for 48 hours. The solution was then cooled to r.t. and diluted with CH₂Cl₂ and 2M HCl. The aqueous phase was extracted with CH₂Cl₂ (3X). The organics were combined and dried over MgSO₄, filtered while hot, and evaporated under reduced pressure. The crude product was purified by recrystallization from toluene afford 19 in 66% yield (421.5 mg). Spectral data corresponded to that previously described in the literature.¹⁷⁰

¹H NMR (400MHz, Pyridine d₅, 293K, Pyridine-H): 7.05 (2H, dd, J=5.1, 3.6Hz), 7.36 (2H, dd, J=5.1, 1.1Hz), 7.44 (2H, dd, J=3.6Hz, 1.1Hz), 7.64 (4H, d, J=8.6Hz), 7.71 (4H, d, J=8.5Hz).

K₂CO₃ (1.5 equiv, 0.75 mmol, 103.7 mg), Pd(OAc)₂ (2 mol %, 0.01 mmol, 2.2 mg), PCy₃·HBF₄ (4 mol %, 0.02 mmol, 7.4 mg), pivalic acid (30 mol %, 0.15 mmol, 15.3 mg) and 4-bromo-N,N-diphenylaniline (0.5 mmol, 162.1 mg) were weighed to air and placed in a screw-capped vial equipped with a magnetic stir bar. The vial was purged with argon then toluene (1.7 mL, 0.3 M) and thiophene (5 equiv, 2.5 mmol, 180 µL) were then added. The reaction mixture was then vigorously stirred at 100 °C for 16 hours. The solution was then cooled to rt, diluted with CH₂Cl₂ and H₂O. The aqueous phase was extracted with CH₂Cl₂ (3X). The organics were combined and dried over MgSO₄, filtered, and evaporated under reduced pressure. The crude product was purified by silica gel column chromatography to afford 20 in 86% yield (141.1 mg). Spectral data corresponded to that previously described in the literature.¹⁷¹

¹H NMR (400MHz, CDCl₃, 293K, TMS): 6.99-7.14 (9H, m), 7.20-7.29 (6H, m), 7.47 (2H, d, J=8.5Hz).

Scheme 3.11 (compound 3.21)

K₂CO₃ (1.5 equiv, 3 mmol, 414.6 mg), Pd(OAc)₂ (2 mol %, 0.04 mmol, 9.0 mg), PCy₃·HBF₄ (4 mol %, 0.08 mmol, 29.5 mg) and pivalic acid (30 mol %, 0.6 mmol, 61.3 mg) were weighed to air and placed in a round bottomed pressure vessel equipped with a magnetic stir bar. The tube was purged with argon, and toluene (6.7 mL, 0.3 M) pentafluorobenzene (2 equiv, 4 mmol, 444 µL) and 2-bromothiophene (1 equiv, 2 mmol, 194 µL) were then added. The reaction mixture was then vigorously stirred at 100 °C for 16 hours. The solution was then cooled to rt and diluted with CH₂Cl₂ and filtered over celite. The filtrate was evaporated under reduced pressure and the residue was purified by silica gel column chromatography to afford 21 in 86% yield (430 mg). Spectral data corresponded to that previously described in the literature.¹⁷²

¹H NMR (400MHz, CDCl₃, 293K, TMS): 7.17-7.21 (1H, m), 7.51-7.54 (1H, m), 7.55 (1H, dd, J=5.2, 1.1Hz)

8.4 Site Selective sp² and sp³ Palladium-Catalyzed Direct Arylation

General Methods:

Picoline N-oxide was purchased from Aldrich and used without further purification. Reagent grade dichloromethan and HPLC grade toluene were used without further purification. Palladium sources and ligands were purchased from Strem and stored in a dessicator and were weighed out to air unless otherwise specified. All other reagents and solvents were used as is from commercial sources. All reactions were performed in air-dried glassware. Coupling reactions were performed with regard for

exclusion of ambient air. Microwave heating was performed using a CEM Discover Microwave (specific reaction conditions are described below). Analysis of crude reaction mixture was done using TLC or NMR. Reactions were purified by flash chromatography on silica gel.

5-Chloroindole (755mg, 1 equiv.) and crushed KOH (1.12g, 4 equiv.) were placed in a round bottom flask equipped with a magnetic stir bar. DMSO was added (17mL, 0.5M) and the reaction was left stirring at room temperature for 120 minutes. Methyl iodide was then added in one portion (710mg, 1 equiv.) and the reaction was left stirring at room temperature for 8 hours. The reaction mixture was then diluted with NH₄Cl and extracted with Et₂O:EtOAc (1:1). The organics were washed with H₂O and Brine and re-extracted with Et₂O and the organic residue was dried over MgSO₄ and evaporated under reduced pressure. The product was purified by silica gel column chromatography using 10% Ether in Hexanes to afford the compound in 79% yield as a yellow oil.

**¹H NMR (400MHz, CDCl₃, 293K, TMS):** 3.77 (3H, s), 6.41 (1H, dd, J=3.1, 0.6Hz), 7.06 (1H, d, J=3.1Hz), 7.16 (1H, dd, J=8.7, 2.0Hz), 7.22 (1H, d, J=8.7Hz), 7.58 (1H, d, J=1.9Hz)

**¹³C NMR (100MHz, CDCl₃, 293K, TMS):** 33.0, 100.6, 110.2, 120.2, 121.8, 125.1, 129.4, 130.1, 135.1

**IR (νmax/cm⁻¹):** 2942, 1512, 1476, 1277, 1062, 751

**HRMS calculated for C₉H₈ClN (M+):** 165.0345 Found: 165.0345

**Rf:** 0.35 (10%Et₂O, 90% Hexanes)

**Oxidation Procedure:** All N-oxides were prepared using an adapted methyltrioxorhenium oxidation protocol first reported by Sharpless and co-workers.¹⁷³ The azine is dissolved in reagent grade CH₂Cl₂ (2.5M). This mixture is added MeReO₃ (1-4mol%) which usually results in a significant color change to deep yellow. This solution is then capped with a rubber septa which is pierced with a small needle as a vent and placed in an ice bath. To the cold solution is added dropwise a 50w% aqueous solution of H₂O₂ (2 equiv.). Once all peroxyde has been added, the reaction is allowed to warm to room temperature where it is stirred for 12-24h. After consumption of starting material, a small amount of MnO₂ (5-10mg) is added to destroy unreacted peroxyde. After stirring this solution of 1-2 hours (until bubbling stops) the mixture is poured into an extraction funnel where the phases are seperated. The aqueous phase is washed with two volumes of CH₂Cl₂ and the organic are combined, dried with MgSO₄, filtered and concentrated under reduced pressure. The N-oxides were then purified via silica gel column chromatography using 5%MeOH/CH₂Cl₂ as the eluent to afford the corresponding N-oxide in 60-90% yield.

**Caution:** Pyridine N-oxides have been shown to exothermically decompose at very high temperature. Uncontrolled heating of the reaction media should be avoided!!

Obtained in 80% yield as a white solid.

RF: 0.16 (20%Et$_2$O, 80% Pet. Ether)

$sp^3$ Direct Arylation Procedures:

Procedure A: Using Microwave Irridiation

All reactions were performed on 0.6 mmol scale: Pd$_2$dba$_3$ (0.025 equiv.), X-Phos (0.05 equiv.), NaO'Bu (3 equiv.), and azine N-oxide (1.5 equiv.) are weighed to air and placed in a microwave tube with a magnetic stir bar (if the aryl halide is a solid, it is also added). The flask is capped with a rubber septa and purged with argon. The aryl halide (1 equiv.) is then added via syringe followed by degassed (with Argon) ACS grade toluene (0.5-1.0M). The rubber septa is then replace by a microwave tube cap and the mixture is then placed in the a CEM Discover microwave reactor at 110°C for 30-45 minutes (conditions: max. power: 200W; T°: 110°C; max. pressure: 250 psi). The reaction is then diluted with 50mL of DCM and filtered through celite then evaporated under reduced pressure. The residue is then loaded onto a silica gel column for chromatography typically using DCM/Acetone/MeOH mixtures.

Procedure B: Using Conventional Heating

All reactions were performed on 0.6 mmol scale: Pd$_2$dba$_3$ (0.025 equiv.), S-Phos or Ru-Phos (0.1 equiv.), NaO'Bu (3 equiv.), and Azine N-oxide (2 equiv.) are weighed to air and placed in a test-tube with a magnetic stir bar (if the aryl halide is a solid, it is also added). The flask is capped with a rubber septa and purged with argon. The aryl halide (1 equiv.) is then added via syringe followed by degassed (with Argon) ACS grade toluene (0.3M). The mixture is then placed in an oil bath and the heat source is set to 69°C. Reactions were left stirring at this temperature for 12-15hours (overnight, reaction times were not optimized). The reaction is then diluted with 50mL of DCM and filtered through celite then evaporated under reduced pressure. The residue is then loaded onto a silica gel column for chromatography typically using DCM/Acetone/MeOH mixtures.

HRMS calculated for C$_{15}$H$_{17}$NO (M+) 214.1166; Found: 214.1166;

m.p.: 95-97 ºC (CHCl$_3$)

Rf: 0.20 (2%MeOH, 10% Me$_2$CO, DCM)

Table 4.3, Entry 7

This compound was obtained in 64% yield as a light yellow oil by following the general $sp^3$ direct arylation procedure with the exception of using 3 eq. of the N-oxide and S-Phos.

$^1$H NMR (400MHz, CDCl$_3$, 293K, TMS): 2.14-2.22 (1H, m), 2.28 (3H, s), 2.59-2.69 (1H, m), 2.99, (1H, ddd, J=16.4, 9.2, 2.1Hz), 3.15-3.24 (1H, m), 4.71 (1H, dd, J=9.2, 1.3Hz), 6.69-7.19 (6H, m), 8.01, (1H, d, J=6.2Hz);

$^{13}$C NMR (100MHz, CDCl$_3$, 293K, TMS): 21.0, 30.3, 32.9, 47.0, 122.2, 124.5, 127.0, 129.3, 136.2, 138.0, 138.4, 142.5, 154.1;

IR ($\nu_{\text{max}}$/cm$^{-1}$): 3083, 2843, 1603, 1444, 1257, 1013

HRMS calculated for C$_{15}$H$_{15}$NO (M+) 225.1159; Found: 225.1140;

Rf: 0.10 (1%MeOH, 10% Me$_2$CO, DCM)

$sp^2$ Direct Arylation Procedures:
Pd(OAc)$_2$ (5 mol%), $^3$Bu$_3$HBF$_4$ (6 mol%), potassium carbonate powder (K$_2$CO$_3$, 1.5 equiv.), aryl halide (1 equiv.) and proper azine N-oxide (1.1-4 equiv.) are weighed to air and placed inside the flask. The flask is then fitted with a reflux condenser which is capped with a rubber septum. The whole setup is then evacuated under vacuum and refilled with Argon four times. Toluene (0.15M) is then added under a steady flow of argon. After addition, the reaction is immersed in the oil bath. Stirring is commenced and the heating source is turned on (set to 125°C). The reaction is left stirring for 12-18 hours (overnight), then allowed to cool, diluted with DCM and filtered over celite. The residues are then purified using silica gel chromatography.

Table 4.4, Entries 1 and 2

![Chemical structure](image)

Obtained in 54% yield as a tan solid.

$^1$H NMR (500MHz, CDCl$_3$, 293K, TMS): 2.41 (3H, s), 2.57 (3H, s), 7.18 (1H, t, J=7.8Hz), 7.22 (1H, dd, J=7.8Hz and 1.9Hz), 7.26-7.31 (3H, m), 7.70 (2H, d, J=8.3Hz);

$^{13}$C NMR (100MHz, CDCl$_3$, 293K, TMS): 18.7, 21.4, 124.6, 124.8 (br), 128.8, 129.3, 130.5, 139.3, 149.5, 149.8;

8.5 Rhodium(III)-Catalyzed Intermolecular Hydroarylation of Alkynes

General Methods:

All rhodium catalyzed hydroarylations of alkynes were carried out with no precautions to exclude ambient oxygen or moisture. The compounds; Cp*Rh(MeCN)\(_3\)(SbF\(_6\))\(_2\),\(^{176}\) cyclopropylethylnyl)benzene,\(^{177}\) 2-(hex-1-ynyl)thiophene,\(^{178}\) 1-(hex-1-ynyl)cyclohex-1-ene,\(^{179}\) tert-butylidimethyl(5-phenylpent-4-ynyl)oxy)silane,\(^{180}\) dimethyl 1H-pyrrole-3,4-dicarboxylate,\(^{181}\) 1-methoxy-4-(prop-1-ynyl)benzene,\(^{182}\) were prepared via literature procedures. All other reagents and solvents were used as received from commercial sources. Unless noted below, all other compounds have been reported in the literature or are commercially available.

Prepared according to the procedure of Suárez and Fu\textsuperscript{183} to afford the product in 45% yield as a yellow oil. 1.0 equivalent of pyridinium tribromide was used to eliminate the allene isomer. Crude product was purified by chromatography on silica gel (6-9% Et<sub>2</sub>O/Petroleum Ether).

\textsuperscript{1}H NMR (400MHz, CDCl<sub>3</sub>, 293K, CHCl<sub>3</sub>): 1.32 (3H, t, \(J=7.1\)Hz), 3.57 (2H, s), 4.24 (2H, q, \(J=7.1\)Hz), 7.16-7.26 (2H, m), 7.38 (1H, dd, \(J=1.5, 8.0\)Hz), 7.48 (1H, dd, \(J=2.0, 7.4\)Hz);

\textsuperscript{13}C NMR (100MHz, CDCl<sub>3</sub>, 293K, CHCl<sub>3</sub>): 14.1, 26.9, 61.7, 80.3, 86.7, 122.9, 126.3, 129.2, 133.5, 136.0, 167.9;

IR (\(\nu_{max}/\text{cm}^{-1}\)): 2984, 1744, 1474, 1181, 1034, 756;

HRMS calculated for C<sub>12</sub>H<sub>11</sub>ClO<sub>2</sub> (M+) 222.0448; Found: 222.0448;

Rf: 0.28 (5:95, Et<sub>2</sub>O:Petroleum Ether)

A 50 mL round bottomed flask was charged with 2,2,2-Trifluoroethylamine Hydrochloride (3 mmol). The flask was then flushed with argon. CH<sub>2</sub>Cl<sub>2</sub> (15 mL), triethylamine (6.6 mmol) and 4-tert-Butylbenzoyl chloride (3.6 mmol) were added to the flask and the resulting solution was allowed to stir at room temperature. After 4 hours the reaction was diluted with CH<sub>2</sub>Cl<sub>2</sub> and washed with 1 M HCl. The organics were dried (MgSO<sub>4</sub>), concentrated and the residue was purified by flash chromatography on silica gel (15% EtOAc/Petroleum Ether) gave the title compound in 97% yield as a white solid.

\textsuperscript{1}H NMR (400MHz, CDCl<sub>3</sub>, 293K, CHCl<sub>3</sub>): 1.33 (9H, s), 4.05-4.16 (2H, m), 6.53 (1H, br s), 7.46 (2H, d, \(J=8.0\)Hz), 7.74 (2H, d, \(J=8.4\)Hz);

\textsuperscript{13}C NMR (100MHz, CDCl<sub>3</sub>, 293K, CHCl<sub>3</sub>): 31.1, 35.0, 41.0 (q, \(J_F=34.7\)Hz), 124.2 (q, \(J_F=278.5\)Hz), 125.7, 127.0, 130.3, 155.9, 167.5;

IR (\(\nu_{max}/\text{cm}^{-1}\)): 3311, 2969,1655, 1503, 1262, 1158;

m.p.: 114-116 °C (CH<sub>2</sub>Cl<sub>2</sub>)

Rf: 0.38 (15:85, EtOAc:Petroleum Ether)

**General Procedure for installation of** \(N,N\)-dimethylcarbamoyl moiety: This procedure has been previously described.\textsuperscript{184} A 100 mL round bottomed flask was charged the indole (10 mmol), NBu<sub>4</sub>HSO<sub>4</sub> (1 mmol) and NaOH (25 mmol). The flask was then fitted with a reflux condenser and flushed with argon. CH<sub>2</sub>Cl<sub>2</sub> (40 mL) and

\textsuperscript{184} Illi, V. O. *Synthesis* 1979, 387.
dimethylcarbamylchloride (15 mmol) were added to the flask and the resulting solution was refluxed for 2-3 hours until the reaction was complete as judged by TLC. The reaction was quenched with saturated NH₄Cl solution. The layers were separated and the aqueous phase was extracted (2x) with CH₂Cl₂. The organics were combined, dried (MgSO₄), concentrated and the residue was purified by flash chromatography.

Compound 5.1a

This compound was obtained in 99% yield as a white solid by following the general procedure for installation of CONMe₂.

**¹H NMR (400MHz, CDCl₃, 293K, TMS):** 3.09 (6H, s), 6.59 (1H, dd, J=0.6, 3.5Hz), 7.19 (1H, ddd, J=1.0, 7.4, 7.6Hz), 7.29 (1H, ddd, J=1.2, 7.7, 7.9Hz), 7.31 (1H, d, J=3.5Hz), 7.59 (1H, d, J=7.8Hz), 7.64 (1H, d, J=8.3 Hz);

**Rf:** 0.30 (70:30, EtOAc:Petroleum Ether)

**General hydroarylation procedure:** Reactions are run without exclusion of ambient air or moisture. A 2 mL screw cap vial was charged with the indole (0.3 mmol), PivOH (5 equiv.), Cp*Rh(MeCN)₃(SbF₆)₂ (5 mol%) and alkyne (1.1 equiv.) if it is a solid. To the vial is added iPrOAc (0.75 mL) and alkyne if it is a liquid. The vial is sealed with a cap and heated at 90 °C for 16 hours. The reaction mixture is loaded onto silica gel and is purified using silica gel chromatography.

**Table 5.2 (Compound 5.3a)**

Rf: 0.50 (15:85 EtOAc:Petroleum Ether)

Table 5.3 (Compound 5.3b)

This compound was obtained in 93% yield as an orange oil by following the general hydroarylation procedure.
$^1$H NMR (400MHz, CDCl$_3$, 293K, CHCl$_3$): 2.30 (3H, d, $J=2.3$Hz), 2.81 (3H, br s), 3.02 (3H, br s), 3.85 (3H, s) 6.60 (1H, s), 6.74 (1H, s), 6.90 (1H, d, $J=2.5$, 8.9Hz), 7.03 (1H, d, $J=2.4$Hz), 7.23-7.29 (1H, m), 7.30-7.41 (1H, m);
$^{13}$C NMR (100MHz, 100MHz, CDCl$_3$, 293K, CHCl$_3$): 17.6, 37.6 (br s), 55.8, 102.5, 104.4, 112.1, 113.2, 126.9, 128.3, 128.5, 128.9, 129.1, 129.2, 131.9, 137.3, 143.0, 154.7, 155.3;
IR ($v_{max}$/cm$^{-1}$): 2928, 2856, 1684, 1389, 1222, 1215, 1033;
HRMS calculated for $C_{21}H_{22}N_2O_2$ (M+) 334.1681; Found: 334.1686;
Rf: 0.32 (20:80 EtOAc:Hexanes)

Table 5.3 (Compound 5.3c)

This compound was obtained in 62% yield as a yellow solid by following the general hydroarylation procedure.
$^1$H NMR (400MHz, CDCl$_3$, 293K, CHCl$_3$): 2.34 (3H, s), 2.74 (3H, br s), 3.19 (3H, br s), 6.81 (1H, s), 6.83 (1H, s), 7.27-7.44 (5H, m), 7.48 (1H, d, $J=9.0$Hz), 8.16 (1H, dd, $J=1.8$, 9.0Hz), 8.53 (1H, d, $J=1.7$Hz);
$^{13}$C NMR (100MHz, 100MHz, CDCl$_3$, 293K, CHCl$_3$): 17.6, 37.0 (br s), 38.0 (br s), 105.1, 111.3, 117.4, 118.9, 127.4, 127.5, 127.7, 128.5, 129.1, 130.9, 136.6, 139.4, 143.1, 145.3, 153.3;
IR ($v_{max}$/cm$^{-1}$): 3085, 2927, 1695, 1514, 1341, 1178;
HRMS calculated for $C_{20}H_{19}N_3O_3$ (M+) 349.1426; Found: 349.1443;
m.p.: 135-138 °C (CH$_2$Cl$_2$)
Rf: 0.28 (20:80 EtOAc:Petroleum Ether)
This compound was obtained in 99% yield as a yellow oil by following the general hydroarylation procedure.

**1H NMR (400MHz, CDCl₃, 293K, TMS):** 2.32 (3H, d, J= 1.3Hz), 2.76 (3H, br s), 3.19 (3H, br s), 3.94 (1H, s), 6.71 (1H, d, J=0.5Hz), 6.83 (1H, s), 7.26-7.31 (1H, m), 7.34-7.42 (4H, m), 7.60 (1H, dd, J=0.4, 8.3Hz), 7.87 (1H, dd, J=1.4, 8.3Hz), 8.12 (1H, s);

**13C NMR (100MHz, CDCl₃, 293K, TMS):** 17.6, 37.0 (br s), 39.0 (br s), 52.0, 104.3, 113.2, 120.2, 122.8, 125.0, 127.3, 128.0, 128.4, 129.2, 130.5, 132.0, 136.0, 136.9, 145.4, 153.9, 167.7;

**IR (νₘₐₓ /cm⁻¹):** 2925, 1695, 1435, 1319, 1242;

**HRMS calculated for C₂₂H₂₂N₂O₃ (M+) 362.1630; Found: 362.1638;**

**Rf:** 0.31(30:70, EtOAc:Hexanes)

---

This compound was obtained in 99% yield as a yellow oil by following the general hydroarylation procedure.

**1H NMR (400MHz, CDCl₃, 293K, CHCl₃):** 2.31 (3H, d, J=1.3Hz), 2.73 (3H, br s), 3.14 (3H, br s), 6.61 (1H, s), 6.78 (1H, s), 7.20 (1H, dd, J=2.0, 8.7Hz), 7.26-7.31 (1H, m), 7.33-7.42 (5H, m), 7.55 (1H, d, J=1.9Hz);

**13C NMR (100MHz, CDCl₃, 293K, CHCl₃):** 17.5, 36.9, 37.7, 103.7, 112.2, 120.0, 123.6, 127.0, 127.1, 128.0, 128.3, 129.1, 129.3, 129.8, 135.0, 137.0, 143.5, 154.1;

**IR (νₘₐₓ /cm⁻¹):** 2924, 1690, 1444, 1390, 1180;

**HRMS calculated for C₂₀H₁₉N₂OCl (M+) 338.1186; Found: 338.1176;**

**Rf:** 0.39 (20:80 EtOAc:Hexanes)

---

This compound was obtained in 71% yield as yellow oil by following the general hydroarylation procedure except 1,2 dichloroethane was used as a solvent for a 24 hour reaction time.
$^{1}H$ NMR (400MHz, CDCl$_3$, 293K, TMS): 2.16 (3H, d, $J$=1.14Hz), 2.96 (6H, br s), 3.82 (3H, s), 3.85 (3H, s), 6.65 (1H, s), 7.24-7.33 (3H, m), 7.34-7.40 (3H, m);
$^{13}C$ NMR (100MHz, CDCl$_3$, 293K, TMS): 18.4, 37.8 (br s), 51.7, 52.3, 115.7, 115.9, 124.4, 127.0, 127.4, 128.3, 129.0, 132.9, 136.6, 138.3, 152.5, 163.5, 165.6;
IR ($\nu_{\text{max}}$/cm$^{-1}$): 3030, 2952, 1716, 1437, 1392, 1206, 1176, 1070;
HRMS calculated for C$_{20}$H$_{22}$N$_{2}$O$_{5}$ (M$^+$) 370.1529; Found: 370.1515;
Rf: 0.37 (50:50 EtOAc:Petroleum Ether)

Table 5.3 (Compound 5.3g)

![Chemical Structure](image)

This compound was obtained in 97% yield as a colorless oil by following the general hydroarylation procedure except using 2 equivalents of arene and 1 equivalent of alkyne.

$^{1}H$ NMR (400MHz, CDCl$_3$, 293K, TMS): 2.60 (6H, br s), 3.72 (3H, s), 3.82 (3H, s), 6.92 (1H, s), 7.04-7.10 (2H, m), 7.10-7.15 (3H, m), 7.16-7.21, (2H, m), 7.21-7.26 (3H, m), 7.34 (1H, s);
$^{13}C$ NMR (100MHz, CDCl$_3$, 293K, TMS): 36.4 (br s), 38.6 (br s), 51.6, 52.3, 115.4, 118.3, 125.0, 127.6, 128.0, 128.1, 128.2, 129.5, 130.1, 130.4, 132.7, 136.0, 136.6, 137.3, 151.6, 163.3, 165.7;
IR ($\nu_{\text{max}}$/cm$^{-1}$): 3023, 2950, 2360, 2336, 1716, 1221, 1087, 759;
HRMS calculated for C$_{25}$H$_{24}$N$_{2}$O$_{5}$ (M$^+$) 432.1685; Found: 432.1701;
Rf: 0.50 (50:50 EtOAc:Petroleum Ether)

Table 5.3 (Compound 5.3h)

![Chemical Structure](image)

This compound was obtained in 91% yield as colorless oil by following the general hydroarylation procedure except 1 equivalent of alkyne and 2 equivalents of 2-acetylfuran was used.

$^{1}H$ NMR (400MHz, CDCl$_3$, 293K, TMS): 2.24 (3H, d, $J$=1.4Hz), 2.52 (3H, s), 6.57 (1H, d, $J$=1.7Hz), 6.80 (1H, d, $J$=1.4Hz), 7.23-7.28 (1H, m), 7.36-7.39 (4H, m), 7.48 (1H, d, $J$=1.7Hz);
$^{13}C$ NMR (100MHz, CDCl$_3$, 293K, TMS): 18.6, 27.5, 114.3, 126.9, 128.2, 129.2, 129.8, 131.6, 137.2, 137.3, 144.3, 147.6, 187.8;
IR ($\nu_{\text{max}}$/cm$^{-1}$): 3029, 2924, 1675, 1560, 1356, 887;
HRMS calculated for C$_{15}$H$_{14}$O$_{2}$ (M$^+$) 226.0994; Found: 226.0978;
Rf: 0.32 (10:90 Et$_2$O:Petroleum Ether)
This compound was obtained in 55% yield as white solid by following the general hydroarylation procedure except using Cp*Rh(MeCN)₃(SbF₆)₂ (2.5 mol%) in tAmOH (0.2M) at 70 °C.

**¹H NMR (400MHz, CDCl₃, 293K, TMS):** 2.07 (3H, s), 2.21 (3H, d, J=1.5Hz), 6.48 (1H, br s), 7.14 (1H, dd, J=7.4, 7.4Hz), 7.23-7.30 (3H,m), 7.38-7.45 (4H, m), 7.94 (1H, d, J=7.6Hz), 8.52 (1H, br s); ¹³C NMR (100MHz, CDCl₃, 293K, TMS): 20.7, 25.0, 125.6, 126.1, 128.5, 129.0, 130.0, 130.3, 130.9, 132.3, 137.0, 138.0, 139.6, 140.0, 169.9;

IR (ν_max / cm⁻¹): 3056, 1667, 1522, 1439, 756, 699;
HRMS calculated for C₁₇H₁₇NO (M+) 251.1310; Found: 251.1304;

**m.p.:** 62-65 °C (CH₂Cl₂)
**Rf:** 0.35 (40:60 EtOAc:Petroleum Ether)

---

This compound was obtained in 62% yield as yellow oil by following the general hydroarylation procedure.

**¹H NMR (400MHz, CDCl₃, 293K, TMS):** 2.12 (3H, s), 2.21 (3H, d, J=1.1Hz), 2.33 (3H, s), 6.49 (1H, s), 7.04 (1H, s), 7.10 (1H, d, J=8.2Hz), 7.27-7.43 (5H, m), 8.02 (1H, d, J=8.3Hz);

**¹³C NMR (100MHz, CDCl₃, 293K, TMS):** 19.8, 20.9, 24.6, 121.9, 127.1, 128.4, 128.8, 128.9, 129.0, 131.0, 131.5, 133.9, 135.7, 136.2, 137.1, 168.1;

IR (ν_max / cm⁻¹): 3263, 2927, 1662, 1520, 1299, 698;
HRMS calculated for C₁₈H₁₉NO (M+) 265.1467; Found: 265.1470;
**Rf:** 0.28 (30:70 EtOAc:Petroleum Ether)
This compound was obtained in 78% yield as yellow oil by following the general hydroarylation procedure except using 2 equivalents of arene and 1 equivalent of alkyne.

$^1$H NMR (400MHz, CDCl$_3$, 293K, TMS): 1.23 (9H, s), 3.54-3.86 (2H, m), 6.15-6.21 (1H, m), 6.94 (1H, d, J=2.1Hz), 6.96 (1H, d, J=3.8Hz), 7.11-7.15 (3H, m), 7.18 (1H, s), 7.22 (1H, d, J=2.0Hz), 7.27-7.33 (4H, m), 7.47 (1H, dd, J=2.0, 8.2Hz), 7.79 (1H, d, J=8.2Hz);

$^{13}$C NMR (100MHz, CDCl$_3$, 293K, TMS): 31.0, 34.8, 40.9 (q, J$_F$=34.6Hz), 123.9 (q, J$_F$=278.6Hz), 125.0, 126.7, 127.4, 128.0, 128.2, 128.6, 129.2, 129.3, 129.6, 131.6, 136.5, 137.7, 141.2, 141.4, 155.2, 158.1;

**Procedure for removal of dimethylcarbamoyl moiety**

Scheme 5.4

(E)-N,N-dimethyl-2-(1-phenylprop-1-en-2-yl)-1H-indole-1-carboxamide (0.164 mmol) was charged to a 4 mL screw capped vial. To the vial was then added 2.8 mL of Ethanol (99%) and 0.9 mL of saturated aqueous KOH solution. The vial was then capped and the mixture stirred at 80 °C for 16 hours. The solution was then diluted with NH\(_4\)Cl solution and EtOAc. The phases were separated and the aqueous phase was reextracted with EtOAc. The organics were combined, dried (brine, MgSO\(_4\)) and concentrated. The residue was purified via flash chromatography over silica gel to give the above compound in 85% yield as white solid.

\(^1^H\) NMR (400MHz, CDCl\(_3\), 293K, TMS): 2.34 (3H, d, J=1.3Hz), 6.67 (1H, dd, J=0.7, 2.0Hz), 6.91 (1H, d, J=1.1Hz) 7.10 (1H, ddd, J=1.0, 7.4, 7.5Hz), 7.19 (1H, ddd, J=1.2, 7.6, 7.6Hz), 7.24-7.30 (1H, m), 7.34-7.41 (5H, m), 7.59 (1H, d, J=7.9Hz), 8.27 (1H, br s);

\(^1^C\) NMR (100MHz, CDCl\(_3\), 293K, TMS): 16.2, 101.6, 110.6, 120.0, 120.6, 122.7, 124.5, 126.8, 128.3, 128.8, 129.2, 136.7, 137.3, 140.2;

IR (\(\nu_{\text{max}} / \text{cm}^{-1}\)): 3421, 1443, 1433, 1299, 796, 753;

HRMS calculated for C\(_{17}\)H\(_{15}\)N (M+) 233.1204; Found: 233.1210;

m.p.: 135-140 °C (CH\(_2\)Cl\(_2\));

Rf: 0.39 (20:80 CH\(_2\)Cl\(_2\):Petroleum Ether)
A 2 mL screw cap vial was charged with 5-Methoxy-N,N-dimethyl-1H-indole-1-carboxamide (0.2 mmol), N,N-dimethyl-5-nitro-1H-indole-1-carboxamide (0.2 mmol), PivOH (1 mmol) and Cp*Rh(MeCN)3(SbF6)2 (0.01 mmol). To the vial was then added iPrOAc (0.75 mL) and 1-Phenyl-1-propyne (0.1 mmol). The vial is sealed with a cap and heated at 90 °C for 16 hours. 1H NMR of the crude reaction mixture revealed a 4:1 ratio in favor of the OMe product.

8.6 Kinetic Resolution of β-Hydroxy Esters

General Procedure for the Preparation of Aryl Malonic Acids:

A neat solution of 2,2-dimethyl-1,3-dioxane-4,6-dione (1.0 equiv.) and phenol (1.0 equiv.) was refluxed at 120°C for 2 hours, and then cooled to room temperature. The reaction mixture was placed under reduced pressure, and loaded directly on a silica gel column (30% EtOAc in hexanes) for purification.

3-oxo-3-phenoxypropanoic acid
This compound was obtained in 75% yield as a white solid by following the general procedure for the preparation of phenyl malonic acid. Spectral data corresponds to that previously described in the literature.185

3-(4-methoxyphenoxy)-3-oxopropanoic acid
This compound was obtained in 81% yield as a beige solid by following the general procedure for the preparation of phenyl malonic acid.

\[ \text{H NMR (300MHz, CDCl}_3, 293K, \text{TMS): } 3.68 (2H, s), 3.81 (3H, s), 6.87-6.93 (2H, m), 7.03-7.08 (2H, m), 8.40 (1H, b); \]

\[ \text{IR (vmax /cm}^{-1} \text{: } 3113, 3056, 2988, 2962, 2951, 2839, 1751, 1715, 1515, 1436, 1277, 1186, 1100, 1033, 845, 657; \]

\[ \text{HRMS calculated for C}_{10}\text{H}_{10}\text{O}_{5} \text{(M+) 210.0528; Found : 210.0511.} \]

M.P. = 88-90 °C
Rf = 0.09 on silica gel (30% EtOAc in hexanes)

3-(4-cyanophenoxy)-3-oxopropanoic acid
This compound was obtained in 27% yield as a white solid by following the general procedure for the preparation of phenyl malonic acids.

\[ \text{H NMR (400MHz, CDCl}_3, 293K, \text{TMS): } 3.72 (2H, s), 7.26-7.31 (2H, m), 7.71-7.74 (2H, m), 9.15 (1H, b); \]

\[ \text{HRMS calculated for C}_{10}\text{H}_7\text{N}_1\text{O}_4 \text{(M+) 205.0375; Found : 205.0376.} \]

M.P. = 76-80 °C
Rf = 0.06 on silica gel (30% EtOAc in hexanes)

2-methyl-3-oxo-3-phenoxypropanoic acid
2,2,5-Trimethyl-1,3-dioxane-4,6-dione (2.0 g, 12.6 mmol, 1.0 equiv.) and phenol (1.19 g, 12.6 mmol, 1.0 equiv.) were weighed into a round bottom flask equipped with a magnetic stir bar and a condenser. The flask was purged with nitrogen and the reaction mixture was heated to 120 °C for 2 h, and then cooled to room temperature. The crude reaction mixture was then loaded directly on a silica gel column for purification (40% EtOAc in hexanes) to give the product as a white solid in 81% yield. Spectral data corresponds to that previously described in the literature.\textsuperscript{186}

**1-ethyl 3-phenyl 2-methylmalonate**

A 100 mL round-bottom flask was charged with 2-methyl-3-oxo-3-phenoxypropanoic acid (1.94 g, 10 mmol), CH$_2$Cl$_2$ (35 mL) and EtOH (584 µL, 10 mmol) under argon atmosphere. N,N'-dicyclohexylcarbodiimide (3.09 g, 15 mmol) and 4-dimethylaminopyridine (122 mg, 1 mmol) were then added to the solution. The resulting solution was allowed to stir at room temperature for 15 hours. The reaction was then filtered through celite and washed with CH$_2$Cl$_2$. The filtrate was then concentrated and the resulting residue was purified via silica gel chromatography (5% EtOAC in petroleum ether) to afford the title compound in 84% yield as a clear oil.

$^1$H NMR (400MHz, CDCl$_3$, 293K, TMS): 1.32 (3H, t, J=7.1Hz), 1.55 (3H, d, J=7.3), 3.68 (1H, q, J=7.3Hz), 4.26 (2H, q, 7.1Hz), 7.08-7.12 (2H, m), 7.25 (1H, d, J=7.3Hz), 7.36-7.41 (2H, m);

$^{13}$C NMR (100MHz, CDCl$_3$, 293K, TMS) : 13.5, 14.1, 46.2, 61.6, 121.2, 126.0, 129.4, 150.5, 168.7, 169.7;

HRMS calculated for C$_{12}$H$_{14}$O$_4$ (M+) 222.0892; Found: 222.0884.

Rf = 0.9 on silica gel (5% EtOAc in petroleum ether);

**General Procedure for the Decarboxylative Addition of Aryl Malonic Acids to Ketones:**

A round-bottom flask is charged with the malonic acid half ester (1.0 equiv.), to which THF (0.5 M with respect to the malonic acid half ester) is added. Triethylamine (1.0 equiv.) and the electrophile (1.0 equiv.) are added via syringe. The resulting mixture is stirred at RT-50 °C for 4-6 hours. Upon completion, the solvent was evaporated in vacuo and the reaction mixture was loaded directly on a silica gel column for purification.

**General Procedure for the Kinetic Resolution of Aldol Products:**

A round-bottom flask is charged with substrate (0.5 mmol), (1S,2R)-N-Methylephedrine (0.3-1 mmol), and toluene (2.5 mL). The reaction vessel was then sealed and the resulting solution was stirred at RT-60 °C for 15-30 hours. Solvent was then removed in vacuo and the resulting residue was purified via column chromatography.
Table 6.2, Entry 1 (Compound 6.3)

\]

7.7 mL of a LiHMDS (7.7 mmol) solution (1M in THF) was cooled to -78 °C in a 25 mL round bottom flask under argon atmosphere. S-Phenyl thioacetate (948 µL, 7 mmol) was added to the solution dropwise and allowed to stir at -78 °C for 1 hour. TMSCl (974 µL, 7.7 mmol) was then added and the resulting mixture was allowed to warm to room temperature over the course of 1 hour. The reaction was then quenched with 8 mL of 0.1M HCl. The organic layer was separated and washed with 10 mL of 0.1M HCl. The aqueous extracts were combined and extracted with petroleum ether (2x). The organics were combined, dried (MgSO\(_4\)) and concentrated. The resulting residue was used directly in the next step. A 100 mL round bottom flask was charged with magnesium bromide etherate (3.9 g, 15 mmol), butyraldehyde (448 µL, 5 mmol) and CH\(_2\)Cl\(_2\) (30mL). The resulting suspension was allowed to stir for 5 minutes, then it was cooled to -78 °C. Trimethyl(1-(phenylthio)vinyloxy)silane (1.57g) in CH\(_2\)Cl\(_2\) (20 mL) was cooled to -78 °C and then added to the reaction. The reaction was allowed to stir at -78 °C for 1 hr 40 min, then warmed to room temperature and allowed to stir for 2 hours. The reaction was then quenched with a saturated NaHCO\(_3\) solution. The layers were separated and the aqueous phase was extracted with EtOAc. The organics were combined, washed with brine and dried (MgSO\(_4\)). The resulting residue was purified via silica gel chromatography (10% EtOAc in petroleum ether) to afford the title compound in 52% yield as a light yellow oil. Spectral data corresponded to that previously described in the literature.\textsuperscript{189} Racemic mixture was resolved by following the general procedure for the kinetic resolution of aldol products. \([\alpha]^{20}_D = -19.4\) (\(c = 1.21\), CHCl\(_3\), 88/12 er);

**Chiral HPLC:** Chiralcel OJ-H, iPrOH/hexane = 10/90, 0.8 mL/min, 210 nm, \(t_{major} = 24.72\) min, \(t_{minor} = 26.71\) min;

Table 6.2, Entry 10 (Compound \textit{6.25})

\[\text{O} \quad \overset{10\% \text{Pd/C}}{\text{Me}} \quad \overset{\text{NET\(_3\), tAmOH}}{\text{R.T. 15 hr}} \quad \overset{\text{O}}{\text{Me}} \quad \overset{\text{O}}{\text{Et}} \]

\[\overset{\text{O} \quad \overset{10\% \text{Pd/C}}{\text{Me}} \quad \overset{\text{NET\(_3\), tAmOH}}{\text{R.T. 15 hr}} \quad \overset{\text{O}}{\text{Me}} \quad \overset{\text{O}}{\text{Et}} \]

---

The title compound was prepared by a modification of a previously reported procedure. A 100 mL round bottom flask was charged with 1-ethyl 3-phenyl 2-methylmalonate (1.11 g, 5 mmol), 10% Pd/C (333 mg, 30% by weight of the substrate). The flask was then capped with a septum and purged with O₂. tert-Amyl alcohol (20 mL) and NEt₃ (766 µL 5.5 mmol) were then syringed into the flask. The resulting solution was allowed to stir at room temperature for 15 hours. The reaction was then filtered through celite and washed with EtOAc. The filtrate was washed with saturated NH₄Cl solution. The aqueous phase was then extracted with EtOAc (2x). The organics were combined, dried (MgSO₄) and concentrated. The resulting residue was purified via silica gel chromatography (10% EtOAc in petroleum ether) to afford the title compound in 48% yield as a clear oil. Spectral data corresponded to that previously described in the literature.

**Chiral HPLC:** Chiralcel OJ-H, iPrOH/hexane = 10/90, 0.8 mL/min, t_major = 26.10 min, t_minor = 21.13 min;

Table 6.3, Entry 2

This compound was obtained in 73% yield as a clear oil by following the general procedure for the deacarboxylative addition of aryl malonic acids to ketones.

**¹H NMR (400MHz, CDCl₃, 293K, TMS):** 1.29 (3H, t, J=7.1Hz), 1.50 (3H, s), 2.90 (1H, d, J=16.3Hz), 3.19 (1H, d, J=16.3Hz), 3.77 (3H, s), 3.82 (1H, b), 4.19-4.32 (2H, m), 6.84-6.88 (2H, m), 6.96-7.00 (2H, m);

### Procedure for Kinetic Resolution on Gram Scale:

A 50 mL round bottom flask was charged with 15 (1 g, 3.96 mmol), (1S,2R)-N-Methylephedrine (14, 1.42 g, 7.92 mmol), and toluene (20 mL). The reaction vessel was then sealed and the resulting solution was stirred at 60 °C for 29 hours. Solvent was then removed in vacuo and the resulting residue was purified via column chromatography (10% EtOAc in hexanes to 50% EtOAc in Acetone) to yield 49% of (+)-15 (94/6 er), 43% 24 (25/1 dr) and 37.5% 14.

**Equation 6.2 (Compound 6.26)**

Recovered in 43% yield and 25/1 dr as a light yellow oil by following the procedure for kinetic resolution on gram scale.

**1H NMR (400MHz, CDCl₃, 293K, TMS):** 1.03 (3H, d, J=6.7Hz), 1.18 (3H, t, J=7.1Hz), 1.46 (3H, s), 2.31 (6H, s), 2.72-2.81 (2H, m), 3.01 (1H, d, J=15.3Hz), 4.16 (2H, q, J=7.1Hz) 6.05 (1H, d, J=4.7Hz), 7.23-7.28 (3H, m), 7.30-7.35 (2H, m);

### Scheme 6.2, Equation 6.4

**1-ethyl 4-phenyl 2-(tert-butyldimethylsilyloxy)-2-methylsuccinate**

A 10 mL round bottom flask was charged with 1-ethyl 4-phenyl 2-hydroxy-2-methylsuccinate (252 mg, 1 mmol), 2,6-dimethylpyridine (128 µL, 1.1 mmol) and CH₂Cl₂ (2mL) under argon atmosphere. The solution was cooled to 0 °C. TBSOTf (253 µL, 1.1 mmol) was then added. The solution was allowed to warm to room temperature
and then stirred for 4.5 hours. The reaction was then quenched with saturated NH$_4$Cl solution. The mixture was then extracted with CH$_2$Cl$_2$. The organics were combined, dried (MgSO$_4$) and concentrated. The resulting residue was purified via silica gel chromatography (5-8% Et$_2$O in petroleum ether) to afford the title compound in 60% yield as a clear oil.

$^1$H NMR (400MHz, CDCl$_3$, 293K, TMS): 0.16 (6H, d, J=5.6Hz), 0.89 (9H, s), 1.28 (3H, t, J=7.1Hz), 1.58 (3H, s), 2.89 (1H, d, J=14.7Hz), 3.15 (1H, d, J=14.7Hz), 4.16-4.27 (2H, m), 7.06 (2H, d, J=8.3Hz), 7.21 (1H, t, J=7.4Hz), 7.35 (2H, t, J=7.9Hz);

$^{13}$C NMR (100MHz, CDCl$_3$, 293K, TMS): -2.9, -2.7, 14.2, 18.3, 25.7, 27.0, 47.0, 61.4, 75.8, 121.5, 125.7, 129.3, 150.5, 168.3, 174.0;

IR ($\nu$ max/cm$^{-1}$): 2956, 2857, 1764, 1493, 1202, 1153, 1025, 838;

HRMS calculated for C$_{15}$H$_{21}$O$_5$Si (M$^+$ - tBu) 309.1153; Found: 309.1157.

Rf = 0.28 on silica gel (5% Et$_2$O in petroleum ether);

**Identification of Absolute Stereochemistry**

Absolute stereochemistry of (+)-2-hydroxy-2-methyl-succinic acid 1-ethyl ester 4-phenyl ester ($\text{6.15}$)

\[
\begin{align*}
\text{(+)-15} & \xrightarrow{\text{KOH (10 mol%)}} \text{EtO} & & \text{EtO} \\
94/6 \text{ er} & \xrightarrow{\text{EtOH}} & \text{EtO} & \xrightarrow{\text{EtO}} \\
\text{Me} & & \text{Me} & \\
\text{CO$_2$Et} & & \text{CO$_2$Et} & \\
\text{OH} & & \text{OH} & \\
\end{align*}
\]

(R)-15 is the recovered enantiomer

2-Hydroxy-2-methyl-succinic acid 1-ethyl ester 4-phenyl ester (0.4 mmol, 94/6 er) and KOH (0.04 mmol) was stirred in 1 mL of ethanol for 2 hours. The solvent was removed in vacuo and the product was isolated using preparatory TLC (20% EtOAc in hexanes) in 34% yield. Spectral data corresponded to that previously described in the literature.$^{189}$ Comparison of the optical rotation data to literature values$^{192}$ show the R enantiomer to be in excess.
