## NOTICE

The quality of this microform is heavily dependent upon the quality of the original thesis submitted for microfilming. Every effort has been made to ensure the highest quality of reproduction possible.

If pages are missing, contact the university which granted the degree.

Some pages may have indistinct print especially if the original pages were typed with a poor typewriter ribbon or if the university sent us an inferior photocopy.

Reproduction in full or in part of this microform is governed by the Canadian Copyright Act, R.S.C. 1970, c. C-30, and subsequent amendments.

## AVIS

La qualité de cette microforme dépend grandement de la qualité de la thèse soumise au microfilmage. Nous avons tout fait pour assurer une qualité supérieure de reproduction.

S'il manque des pages, veuillez communiquer avec l'université qui a conféré le grade.

La qualité d'impression de certaines pages peut laisser à désirer, surtout si les pages originales ont été dactylographiées à l'aide d'un ruban usé ou si l'université nous a fait parvenir une photocopie de qualité inférieure.

La reproduction, même partielle, de cette microforme est soumise à la Loi canadienne sur le droit d'auteur, SRC 1970, c. C-30, et ses amendements subséquents.

## ABSTRACT

The intermetallic phase,  $\text{Na}_4\text{Sn}$ , can be synthesised by a solid state reaction starting from stoichiometric quantities of the elements. It crystallizes in the orthorhombic space group  $Pnam$  with 4 asymmetric units per unit cell ( $a=9.744(3)\text{\AA}$ ,  $b=22.751(10)\text{\AA}$ ,  $c=5.5390(15)\text{\AA}$ ). The reactivity of  $\text{Na}_4\text{Sn}$  with organic and inorganic halides, elements and organic cations was investigated.

The interconversion between  $\text{P}_{21}^{3-}$  and  $\text{P}_{16}^{2-}$  has been demonstrated. Coordinating solvents, such as THF and pyridine, stabilise the more reduced  $\text{P}_{21}^{3-}$  while the less reduced  $\text{P}_{16}^{2-}$  is favored when a non-coordinating solvent like EtOH is used. The reaction of  $\text{P}_{21}^{3-}$  with  $\text{Bu}_3\text{SnCl}$  yields the new polyphosphides  $\text{P}_{14}^{2-}$ . The structure of this new anion was deduced from  $^{31}\text{P}$  studies.

**ACKNOWLEDGEMENTS**

I would like to thank Professor D. Richeson for his help during the last two years. Without him this work would not have been possible.

I would also like to thank Professor S. Gambarotta for his fruitful suggestions throughout this research.

Finally, I would like to thank my co-workers for their support.

## INTRODUCTION

The last few decades have seen a growing interest in the synthesis and characterization of the binary and ternary compounds formed between the electropositive alkali metals or alkaline earth metals and p-block elements such as Sn, Ge, P, or Te. These compounds are of general interest for several reasons: (i) their unusual structural features (ii) their potential use as starting material for the preparation of useful compounds and (iii) their physical properties related to their stoichiometry and structure.

The products obtained from these reactions can be classified into two major groups with the defining features being the interaction of the metal cation with the reduced p-block element. The first group, which will be referred to as binary or ternary phases, includes all the intermetallic compounds in which isolated molecular units are not found. Although varying degrees of interaction between the constituent atoms are discernable, their structures are infinite and uniform. As a general trend, these materials tend to have a high metal to p-block element ratio. In other words, the p-block element is, in a formal sense, highly reduced. One of the interesting features of these compounds is their covalent character. Recent literature examples include  $\text{Ca}_{31}\text{Sn}_{20}$ <sup>1</sup> and the related  $\text{Sr}_{31}\text{Pb}_{20}$  as well as  $\text{LiSbTe}_2$ <sup>2</sup>.

The second group can be classified as binary anions and is composed of all the molecular anionic species, both in the solid state or in solution. The ionic character of these compounds is greater than for their extended counter parts and may be sufficient to allow solvation of the cation with polar solvents.

Both classes of materials are known for the heavy elements of group 14, 15 and 16<sup>3</sup>. Particular emphasis has been directed toward Sn and Pb in group 14, P in group 15 and S, Se, and Te in group 16. One of the problems associated with structural characterisation of these species has been the difficulty in obtaining crystalline material and, for this reason, multinuclear NMR have been used extensively for their characterisation.

Surprisingly, there have been few studies concerning the reactivity of these species. Their potential use as precursors for the synthesis of semi-conductor materials has recently been demonstrated<sup>4</sup>. They may also provide an entry to new materials and molecules by functioning as ligands for organometallic complexes or as starting materials for the synthesis of inorganic polymers. Such polymers could have interesting electrical or magnetic properties based on the main group core. Ultimately, the polymerisation of these species would help to elucidate the transition between molecules and solid state compounds.

With these facts in mind, we have decided to focus our attention on the compounds containing phosphorus and/or tin as the main group elements. As starting materials for further exploration of the reactivity of these compounds they are among the most thoroughly characterised. In addition, the fact that they possess NMR active nuclei should allow the determination of the structural features of the products without relying on single crystal preparation. Table I shows useful data concerning these nuclei.

Table I Characteristics of  $^{31}\text{P}$ ,  $^{117}\text{Sn}$  and  $^{119}\text{Sn}$

	$^{31}\text{P}$	$^{117}\text{Sn}$	$^{119}\text{Sn}$
Nuclear Spin	1/2	1/2	1/2
Natural abundance (%)	100	7.61	8.58
Receptivity (vs $^{13}\text{C}$ )	377	19.5	25.2
Chemical shift range(a) (ppm)	-500 to 300	(b)	-2000 to 500

(a) Reference to  $\text{Me}_4\text{Sn}$  for  $^{119}\text{Sn}$  and to  $\text{H}_3\text{PO}_4$ , 10% in water for  $^{31}\text{P}$

(b) Because of its higher relative abundance,  $^{119}\text{Sn}$  is generally preferred

The high relative abundance of  $^{31}\text{P}$  makes the homonuclear coupling easy to observe and structures of complex species can be proposed based solely on NMR data. In the case of tin, the presence of two nuclei often results in characteristic splitting pattern even in highly symmetrical species.

In the following sections, a brief overview of the related literature is presented. This is followed by a description of the results of our investigations of the binary and ternary phases and anions of tin and phosphorus.

**CHAPTER 1: STANNIDES**BACKGROUND

The investigation of binary compounds of group 14 with the electropositive elements of groups 1 and 2 goes back to the beginning of the century. The first evidence of their existence was given by Johannis<sup>5</sup> who, while studying the addition of lead to ammonia solutions of sodium, noticed dramatic color changes. Intrigued by these observations, Smyth<sup>6</sup>, Peck<sup>7</sup> and Kraus<sup>(8,9)</sup> began studies of this system but they were not able to explain these observations. Shortly thereafter Zintl<sup>10</sup> reported the first systematic investigation of these ammonia solutions. By employing potentiometric titration of Na/NH<sub>3(l)</sub> with PbI<sub>2</sub>, he was able to identify the polyanions Pb<sub>9</sub><sup>4-</sup> and Pb<sub>7</sub><sup>4-</sup>. However, problems arose due to contamination of the solutions with alkali metal halides and the inability to observe the same effects with lighter elements, such as tin, forced him to search for new synthetic approaches to these compounds.

The first success was achieved by Zintl, Harder<sup>11</sup> and Dullenkopf<sup>12</sup> through the extraction of binary alloys, formed by fusion of the elements, with liquid ammonia. Starting from alloys of composition (Sn,Pb)/Na = 2.25 to 2.75, they were able to extract the homoatomic polyanions M<sub>9</sub><sup>4-</sup> (M=Sn, Pb).

At this point, the investigation of these unusual alloys took two routes. The first approach was directed at obtaining crystalline binary phases directly via solid state synthesis. Recent examples include the high-pressure synthesis of  $\text{LiSi}^{13}$ ,  $\text{LiGe}^{14}$  and  $\text{LiSn}^{15}$ . The second was to focus on the soluble products obtained from extraction of alloys of group 14 and electropositive group 1 elements with amine solvents such as ammonia or ethylenediamine.

Following the first approach, Zintl and Harder investigated the solid state alloys of the  $(\text{Sn}, \text{Pb})/\text{Na}$  system and reported, based on X-ray diffraction, the crystal structures of two isostructural phases of composition  $\text{Na}_{15}\text{Pb}_4$  and  $\text{Na}_{15}\text{Sn}_4$ <sup>16</sup>. These materials were reported to have a body-centered cubic structure with  $a_0=13.32\text{\AA}$  and 76 ( $4 \times 19$ ) atoms per unit cell. This contrasted with a previous report<sup>17</sup> in which a phase of composition  $\text{Na}_{31}\text{Pb}_8$  was reported to have a face centered cubic structure with  $a_0=13.30\text{\AA}$  and 78 ( $2 \times 39$ ) atoms per unit cell. Moreover, earlier thermal analysis work by Mathewson<sup>18</sup>, Boesch and Calingaert<sup>19</sup> indicated the existence of only one phase. In 1955, Shoemaker and co-workers reported the results of their analysis of the Na-Pb system<sup>20</sup>. Using different alloy preparation procedures which included annealing at  $280^\circ\text{C}$  for 60 hours followed by  $\text{N}_2(l)$  quench or slow cooling, they were only able to reproduce Zintl's observation and found only the  $\text{Na}_{15}\text{Pb}_4$  phase. The structure of the related " $\text{Na}_{15}\text{Sn}_4$ " phase was not defined

and the identity of the phase commonly referred to as  $\text{Na}_4\text{Sn}$  remained uncertain.

During the same period of time attempts to follow the second approach, the isolation of soluble polyanions, were unsuccessful. Simply evaporating the solvent only gave amorphous solids. This was believed to be a result of the instability of the solvent free cation which in order to achieve greater stability undergoes a back transfer of electrons from the polyanion to the cation with decomposition of the anion (equation 1a).

The replacement of ammonia with ethylenediamine as the extraction solvent enabled Kummer and Diehl<sup>21</sup> to isolate, for the first time, a crystalline compound with the formula  $[\text{Na}_4(\text{en})_7]\text{Sn}_9$  (en=ethylenediamine). The crystal structure of this compound revealed the naked cluster anion  $\text{Sn}_9^{4-}$  and confirmed the earlier work of Zintl (Figure 1a).

Figure 1a Crystal structure of the naked anion  $\text{Sn}_9^{4-}$

Further attempts to crystallise other polyanions using ethylenediamine to both extract and stabilize the cation were

unsuccessful and it rapidly became obvious that other methods to stabilize the cation had to be found.

In 1968, Corbett<sup>22</sup> showed that the cation complexing agent 2,2,2crypt<sup>23</sup> (Figure 1b) provided the needed stabilisation energy and allowed the crystallisation of a variety

of anions. Table 1A lists some Figure 1b 2,2,2-Crypt of the homopolyatomic anions that were crystallised with the use of crypt.

Table 1A Some group 14 homopolyatomic anions (crypt complexes)

$Pb_5^{2-}$	$D_{3h}$	Ruby-red prisms	12	

\* only known paramagnetic polyatomic anion

Following Corbett's work, Rudolph investigated the synthesis of heteroatomic polyanions with the general formula  $(Sn_{9-x}M_x)^{4-}$  ( $x=0-$

9) by extraction ( $M=Pb^{28}$ ,  $Ge^{29}$ ) or electrolysis ( $M=Pb^{30}$ ) of ternary alloys. All of these investigations were based on multinuclear NMR studies and no crystal structures were reported.

The effectiveness of crypt at cation stabilization also enabled the isolation of mixed element clusters. This not only provided additional structural examples but also allowed the combination of electron poor (group 13) or electron rich (group 15 or 16) elements to form "doped" anions. Table 1B presents some of the known mixed polyanions.

Table 1B Some known "doped" polyanions

Anion	p e <sup>-</sup>	ref
$TlSn_8^{3-}$	20	31
$TlSn_9^{3-}$	22	"
$SnTe_4^{4-}$	22	32
$Sn_2Te_6^{4-}$	32	"
$Sn_2Bi_2^{2-}$	12	33
$SnAs_{14}^{4-}$	48	34

More recently<sup>35</sup>, the use of other alkali metal cation coordinating agents such as HMPA (hexamethylphosphoric triamide) have been demonstrated to provide enough stabilisation to allow the crystallisation of some anions. The replacement of the alkali metal

cation with tetraalkylammonium salts<sup>35</sup>, such as  $\text{Me}_4\text{N}^+$ , has shown some limited success and allowed the isolation of the highly insoluble  $(\text{Me}_4\text{N})_4\text{Sn}_9$ . However, the compounds obtained in these two cases are thermally unstable and decompose slowly at 25°C.

Finally, what is believed to be the "next frontier" in this area is the use of transition metal complexes to stabilise the cluster core. Only one example is known and was given by Huttner<sup>36</sup> in 1993. Starting from  $\text{SnCl}_2$  and  $\text{K}_4[\text{Cr}(\text{CO})_5]$ , he was able to synthesis the first octahedral main group polyanion  $[\text{Sn}_6\{\text{Cr}(\text{CO})_5\}_6]^{2-}$ .

RESEARCH GOALS

1. Investigate the formation of sodium/tin binary alloys in order to provide a better understanding of the mechanisms involved in their formation. This could then allow a better control of their synthesis and ultimately lead to the formation of new species
2. Examine the reactivity of these alloys toward metathesis reactions with both organic and inorganic halides. Such reactions could provide alternative routes for the synthesis of useful compounds which are normally prepared via high temperatures solid state reactions.
3. Study the ability of these alloys to act as precursors for the synthesis of new mixed polyanions by introduction of a third component in the system. The resulting species could possess new and unusual structural features as well as interesting properties.

## RESULTS AND DISCUSSION

### Alloy preparation : synthesis of $\text{Na}_4\text{Sn}$

Several phases are present in the Na/Sn phase diagram (Figure 1c). Among these some controversy exists as to the structure and identity of the compound richest in Na,  $\text{Na}_4\text{Sn}$ . Our investigations of this system began with the preparation of binary alloys by heating, under dynamic  $\text{N}_2(g)$  in a glass tube, the two elements to  $300^\circ\text{C}$  for 30 minutes. The reaction tubes were then cooled, the solid ground and extracted with ethylenediamine or liquid ammonia to remove any soluble species or unreacted metallic sodium. A summary of the reaction conditions used for the synthesis of these alloys is presented in Table 1C.

Figure 1c Na/Sn phase diagram (from: Constitution of binary alloys, second edition, Hansen, McGraw Hill book company, 1958, 1005)

Table 1C Synthesis of Na/Sn alloys : reaction conditions

Stoichiometry	Products	Extraction products
Na/Sn < 3.8/1	black alloys	ethylenediamine : $\text{Sn}_9^{4-}$
Na/Sn = (3.8-4.1)/1	metallic grey crystals	no soluble products were formed
Na/Sn > 4.1/1	crystals	$\text{NH}_3(l)$ : Na

All the sodium-poor alloys, those with a Na/Sn ratio lower than 3.8, gave upon extraction with ethylenediamine or  $\text{NH}_3(l)$ , very dark red solutions for which the  $^{119}\text{Sn}$  NMR showed a 0.060:0.311:1.000:0.309:0.030 pseudo quintet centered at 1230ppm upfield from the tetramethyltin signal (Figure 1d). The calculated relative intensities of the multiplet for a 9 atoms cluster are 0.044:0.311:1.000:0.311:0.044 based on abundances of 8.58% and 7.61% for  $^{119}\text{Sn}$  and  $^{117}\text{Sn}$ , respectively. This signal confirmed that the only soluble Sn compound was the nonastannide tetraanion ( $\text{Sn}_9^{4-}$ )<sup>28</sup>. However, the best yield of  $\text{Sn}_9^{4-}$  were obtained with alloys of composition  $\text{NaSn}_{2.25}$ . As indicated by the phase diagram, pure, congruently melting  $\text{Na}_4\text{Sn}$  should be obtained for the alloys of composition Na/Sn = 4/1. Reaction with this stoichiometry yielded metallic grey crystalline material in quantitative yield. Similar results were obtained when a slight excess sodium was used. However, in these cases, the excess sodium remained unreacted and had to be removed by washing with  $\text{NH}_3(l)$ . DSC studies (Figure 1e) of

the crystals showed, consistent with the phase diagram, a reversible endotherm at 407°C which corresponds to the melting of the compound.

It is important to notice that the melting point of the crystals is higher than the temperature at which they are formed (300°C). A likely explanation may be that the sodium ( $T_m=98^\circ\text{C}$ ) act as a flux, in the early stage of the reaction, there is enough  $\text{Na}_{(l)}$  to dissolve the compound. As the reaction proceeds, the amount of sodium left unreacted is smaller and the solution become saturated and starts to crystallise. Finally, when all the sodium has reacted the compound precipitates. This hypothesis could also explain the higher crystallinity of the products obtained when a slight excess sodium is used.

The  $\text{Na}_4\text{Sn}$  extended structure is based on the asymmetric unit shown in Figure 1f with the tin atoms emphasized to demonstrate the two different environments. The first tin atom ( $\text{Sn1}$ ) lies on one corner of a tetragon completed with three sodium atoms ( $\text{Na4}$ ,  $\text{Na8}$  and  $\text{Na1}$ ), it also forms a pseudo-octahedron with the other five sodium environments ( $\text{Na6}$ ,  $\text{Na5}$ ,  $\text{Na3}$ ,  $\text{Na2}$  and  $\text{Na7}$ ). The other tin atom ( $\text{Sn2}$ ) is sticking out of the asymmetric unit and is attached to  $\text{Na1}$ . A view of one unit cell of  $\text{Na}_4\text{Sn}$  along the  $a$  axis is given in Figure 1g. The unit cell is composed of four asymmetric units with alternating orientation. Expansion to two unit cell along the  $b$  axis (Figure 1h) shows the columnar character of the structure. The  $\text{Sn2}$  atoms bridges between the  $\text{Na1}$  atoms of adjacent asymmetric units forming columns. These columns are then oriented alternatively head-to-head and tail-to-tail to expand the structure in the  $c$  dimension. The position of the  $\text{Sn2}$  atoms relative to the columns is better shown in Figure 1i. This figure also shows the interpenetration of the tetragonal planes of alternating columns.

A few features are striking in the structure: (i) it is not a closest packed structure like one might expect for a simple alloy (ii) there is no significant Sn-Sn interaction (iii) the presence of two different tin environments.

## Reactivity of $\text{Na}_4\text{Sn}$

In order to define the reactivity of  $\text{Na}_4\text{Sn}$  four types of reactions were performed : reactions with elements, inorganic and organic halides and organic cations. The results of these reactions are discussed below.

### Reactions of $\text{Na}_4\text{Sn}$ with elements

The synthesis of mixed main group ternary phases or mixed element anions generally involves high temperature reactions of the elements in sealed tubes. This technique allows very little control of the reaction products and low yields are commonly obtained. The reaction of  $\text{Na}_4\text{Sn}$  with main group elements may provide a more controlled route for the synthesis of such compounds. Our first efforts were directed toward the investigation of the reaction of  $\text{Na}_4\text{Sn}$  with elemental phosphorus and sulfur. The reasons for this are two-fold. First, phosphorus and sulfur are known to make a wide variety of catenated phases and anions. Second, our experience with  $^{31}\text{P}$  NMR spectroscopy<sup>a</sup> in the characterisation of polyphosphides could be of some importance.

Reactions of  $\text{Na}_4\text{Sn}$  with red phosphorus were performed by heating the two powders in a sealed tube at  $150^\circ\text{C}$  for 8 hours. For the reactions with white phosphorus, the  $\text{Na}_4\text{Sn}$  was refluxed in

---

<sup>a</sup> see chapter II, Polyphosphides

toluene solution of white phosphorus for 8 hours. Both procedures yielded black amorphous powders and no diffraction pattern was observed by powder XRD. Addition of ethylenediamine to these powders gave dark orange solutions as well as gas evolution.  $^{119}\text{Sn}$  NMR of the orange solution showed the presence of  $\text{Na}_4\text{Sn}$ , (quintet at  $-1230\text{ppm}$ ) while the  $^{31}\text{P}$  NMR of that same solution showed only one signal at  $-273.1\text{ ppm}$  characteristic of  $\text{NaPH}_2$ <sup>60</sup>. The gas was characterised by mass spectrometry and  $^1\text{H}$  NMR spectroscopy and identified as a mixture of  $\text{MeNH}_2$  and  $\text{EtNH}_2$ <sup>b</sup>.

These observations and the corresponding ones obtained from the reaction of  $\text{Na}_3\text{P}$  with ethylenediamine can be explained by proposing reaction 1b for the interaction of  $\text{Na}_4\text{Sn}$  and  $\text{P}^0$ .

In this reaction the  $\text{Na}_4\text{Sn}$  acts as a reducing agent toward phosphorus to form  $\text{Na}_3\text{P}$  and an alloy containing the remaining sodium and tin. Extraction of this mixture with ethylenediamine results in a simple extraction of a tin-rich Na/Sn alloy to give  $\text{Na}_4\text{Sn}$ , while the  $\text{Na}_3\text{P}$  reacts with the ethylenediamine to form the  $\text{NaPH}_2$ , the  $\text{MeNH}_2$ , and the  $\text{EtNH}_2$ .

Unlike the reactions with elemental phosphorus, the reactions of  $\text{Na}_4\text{Sn}$  with elemental sulfur were extremely violent and self-

---

<sup>b</sup> see discussion on the synthesis  $\text{NaPH}_2$ , for the identification of the products (page 48)

initiated when the two powders were put in contact. The products of these reactions were heterogeneous and amorphous rendering their characterisation nearly impossible.

### Reactions of Na<sub>4</sub>Sn with inorganic halides

Reaction of inorganic halides and reduced main group element compounds may offer an alternative to the high temperature, direct reaction of element commonly employed in solid state synthesis. In these reactions, high  $\Delta H_{\text{reaction}}$  supplies the energy for the propagation. Such solid state metathesis reactions have recently<sup>4</sup> been used in the synthesis of groups III-V semiconductors. Sodium and lithium pnictides, Na<sub>3</sub>E and Li<sub>3</sub>E (E=N, P, As, Sb) react with metal halides such as GaCl<sub>3</sub> or TiCl<sub>4</sub> to form GaE or TiE (equation 1c and 1d).

where M = Ti, Zr, Hf or V<sup>3+</sup>

Metathesis reactions starting from Na<sub>4</sub>Sn and metal halides were explored in an effort to prepare new stannides and to offer alternative methods for the synthesis of known ones. The advantage of such reactions is that they could provide low temperature

alternatives to the high temperature and pressure routes normally involved in the synthesis of these materials.

The phase diagrams for both Al/Sn and Ga/Sn systems are typical of a two component system which does not form any compounds. The reactions of  $\text{Na}_4\text{Sn}$  with  $\text{AlCl}_3$  and  $\text{GaCl}_3$  self-initiated within seconds when the two powders were simply placed in contact of one another. In order to prevent self initiation, the reactions were performed in a two zone tube, with one of the components in each zone. The tube was then sealed under vacuum and the metal halides slowly sublimed into the zone containing the  $\text{Na}_4\text{Sn}$ . Even in these conditions, the reactions were extremely violent and the products heterogenous. Grinding and annealing of the powders did not improve the homogeneity of the products. However, DSC studies allowed the identification of metallic tin as one of the products.

Three compounds are seen in the Nb/Sn phase diagram:  $\text{Nb}_3\text{Sn}$ ,  $\text{Nb}_6\text{Sn}_5$  and  $\text{NbSn}_2$ . Of these,  $\text{Nb}_3\text{Sn}$  is of particular interest due to the fact that it exhibits one of the highest superconducting transition temperatures ( $T_c = 18.05 \text{ K}$ ) for a simple binary alloy. The reactions between  $\text{Na}_4\text{Sn}$  and  $\text{NbCl}_5$  self-initiated upon grinding with a mortar and pestle. In order to obtain homogeneous products, the separate components were placed in a teflon lined acid digestion bomb and the reaction was thermally initiated at  $150^\circ\text{C}$ . The temperature was then held constant for 12 hours after which a

black powder was obtained. Removal of the NaCl from this black powder by successive washing with H<sub>2</sub>O, EtOH and Et<sub>2</sub>O yielded a black powder with a typical composition of Nb<sub>3</sub>Sn. SEM and XRD of the black powder revealed its homogeneous and amorphous nature. Thermal studies showed that heating the sample in an inert atmosphere to 1200°C does not result in an increased crystallinity nor does it cause a decomposition. However decomposition was observed at 500°C when the powder was heated in air. Variable temperature conductivity measurements on the powder showed a temperature dependence of the conductivity (Figure 1j) which is typical of a semiconductor and no drop in resistance was noted near T<sub>c</sub> of 18.05k.

#### Reactions of Na<sub>4</sub>Sn with organic halides

Based on the high reactivity of Na<sub>4</sub>Sn with inorganic halides, one might expect that when put in contact with organic halides, Na<sub>4</sub>Sn would react to eliminate NaCl and form the metathesis SnR<sub>4</sub> products. Moreover, it has been demonstrated<sup>38</sup> that Na<sub>3</sub>P reacts violently with trimethylsilyl chloride to form the phosphine with formation of NaCl. However, as presented in Table 1F, Na<sub>4</sub>Sn did not react with any organic halides. Even under forcing conditions, neat reagent and reflux, the starting materials remained unchanged.

Figure 1j Nb<sub>3</sub>Sn: conductivity vs temperature

Table 1F Summary of the reactions of Na<sub>4</sub>Sn with organic halides

#### Reactions of Na<sub>4</sub>Sn with organic cations

It is well known that some Na/Sn alloys are precursors to soluble polystannide anions<sup>39</sup>. Based on the results of washing the solid with ethylenediamine it was clear that a simple extraction of Na<sub>4</sub>Sn would not work and no soluble species would be formed. However, complete or partial replacement of the sodium cations with organic cations may increase the solubility which could then lead to the formation of new soluble species. The reactions of Na<sub>4</sub>Sn with organic cations were performed by stirring, at room temperature, either THF or ether suspensions containing

stoichiometric amounts of both starting materials. In the cases where no observable reactions were occurring, this was followed by 12 hours of reflux. Table 1G summarizes the results of these reactions with different organic cations.

Table 1G Reactions of  $\text{Na}_4\text{Sn}$  with organic cations

Cation	Reaction conditions	Products
$\text{R}_4\text{N}^+$ (R=Me, Bu)	Refluxing THF (12h)	no reaction
$\text{Me}_3\text{BzN}^+$	"	"
$\text{Et}_3\text{BzN}^+$	RT in THF (1h)	unidentified
$\text{Ph}_4\text{P}^+$	RT in $\text{Et}_2\text{O}$ (12h)	$\text{PPh}_3$ , $\text{PPh}_5$
$(\text{Ph}_3\text{P})_2\text{N}^+$	RT in THF (30m)	$\text{PPh}_3$ + unidentified

As shown in Table 1G, the ammonium salts containing only alkyl substituents such as methyl or butyl did not react with  $\text{Na}_4\text{Sn}$  while the ones with only aryl substituents all reacted quite readily. In the intermediate cases where both alkyl and substituted alkyl substituents were present, a reaction was observed with  $\text{Et}_3\text{BzN}^+$  but not with the methylated equivalent,  $\text{Me}_3\text{BzN}^+$ .

The first reaction to be studied was the reaction between  $\text{Na}_4\text{Sn}$  and the  $\text{Ph}_4\text{P}^+$  cation. Stirring an ether suspension containing  $\text{Na}_4\text{Sn}$  and  $\text{Ph}_4\text{PBr}$  resulted in the formation of a dark orange solution within 12 hours at room temperature. The  $^{31}\text{P}$  NMR of the crude

reaction mixture showed two major signals at  $\delta = -4.9$  and  $-85.1$  ppm (Figure 1k) in a 1:1 ratio. These two resonances were attributed to  $\text{PPh}_3$  and  $\text{PPh}_2$  respectively based on values obtained by  $^{31}\text{P}$  NMR of commercially available samples. The other signals detected in the  $^{31}\text{P}$  NMR spectrum indicated the presence of impurities that might be responsible for the dark orange color of the solution. Recrystallisation from toluene allowed the isolation of  $\text{PPh}_2$  which was further characterised by  $^1\text{H}$  and  $^{31}\text{P}$  NMR, IR and X-Ray crystallography (the preliminary crystal structure is presented in Figure 1l). No soluble Sn compounds were detected by  $^{119}\text{Sn}$  NMR spectroscopy.

For the reaction of  $\text{Na}_4\text{Sn}$  with  $[(\text{Ph}_3\text{P})\text{P}]_2\text{NCl}$ , a color change was observed within 30 minutes. However, unlike the case of  $\text{Ph}_4\text{P}^+$ , the reaction was not quantitative and unreacted starting material was still found after 12 hours of reflux. The  $^{31}\text{P}$  NMR of the orange solution was quite complicated (Figure 1m) and only  $\text{PPh}_3$  ( $\delta = -4.9$  ppm) was identified as one of the products.

Based on these observations, a two step mechanism for the reaction of  $\text{Na}_4\text{Sn}$  with  $\text{Ph}_4\text{P}^+$  salts can be proposed. The first step (equation 1e) involves an electron transfer from  $\text{Na}_4\text{Sn}$  to the organic salts. This generates two equivalents of  $\text{NaX}$ , tin metal,  $\text{PPh}_3$  and the active species ( $\text{NaPh}$ ). The second step (equation 1f) is the reaction of this active species with unreacted organic salts to form the other two equivalents of  $\text{NaX}$  and  $\text{PPh}_2$ .

Figure 1k  $^{31}\text{P}$  NMR of the crude solution from the reaction of  $\text{Na}_4\text{Sn}$  with  $\text{Ph}_3\text{PBr}$

**Figure 1a**  $^{31}\text{P}$  NMR of the crude solution obtained from the reaction of  $\text{Na}_4\text{Sn}$  with bis(triphenylphosphine)ammonium chloride

Step one: electron transfer

Step two: reaction with NaPh

However, for  $(\text{Ph}_3\text{P})_2\text{N}^+$ , the active species must involve less stable imido intermediates which can decompose to other amines or phosphines or react with left over starting material.

The reaction between the  $\text{Et}_3\text{BzN}^+$  cation and  $\text{Na}_4\text{Sn}$  is completed in an hour at room temperature yielding a dark orange solution and a white solid which contained unreacted ammonium salts. Table 1H summarised the results of  $^1\text{H}$  NMR studies of this reaction.

Table 1H  $^1\text{H}$  NMR studies of the  $\text{Et}_3\text{BzN}^+$  reaction

Treatments	Aliphatic signals (ppm) <sup>(a)</sup>		
	A	B	C
Crude reaction mixture	0.98(dt)	1.85(q)	2.15(dd)
Sublimed product	0.98(dt)	1.85(q)	---
reaction in $\text{C}_6\text{D}_6$	---	---	2.15(dd)

(a) aromatic signals omitted for clarity

dt : doublet of triplet

q : quartet

dd : doublet of doublet

The NMR of the crude reaction mixture consisted of what appeared to be a mixture of 2 species, AB and C. Sublimation of this mixture allowed the recovery of only one of the two compounds, AB (Figure 1n). Elemental analysis<sup>c</sup> of this oil gave a composition of C 88.89%, H 6.51% and N 5.02% which correspond to the reduced formula  $C_{21}H_{19}N$  (C 88.38%, H 6.71% and N 4.91%).

If the reaction is performed in benzene instead of diethyl ether, the other product, C, is obtained (Figure 1o). Coupling between the signals A and B as well as between the signals A and C as shown in the  $^1H$  2D COSY NMR (figure 1p) is against the hypothesis of two compounds. Two protons on two different species should not be coupled together and no cross-peaks should be observed between A and C if there are in fact two species.

Attempts to do the reaction using simpler ammonium salts such as tetramethylammonium chloride and tetrabutylammonium bromide or trimethylbenzylammonium chloride were unsuccessful and no reactions were observed. Attempts to explain these results using the mechanism proposed for the reaction of  $Na_4Sn$  with  $PhP_4^+$  were unsuccessful, the formation of a penta coordinated nitrogen being impossible. As of now, the mechanism and the products of these reactions are still unknown and further investigations will be needed.

## CONCLUSIONS

Unlike what might be expected for a simple alloy, the structure of the new intermetallic phase,  $\text{Na}_4\text{Sn}$ , is not a closest packed structure and the two different tin environments is a particularly striking feature. Investigations of its reactivity, with inorganic and organic halides, elements, and organic cations show that it functions mainly as a reducing agent.

Further studies of its uses as a tin precursor in solid state metathesis reactions with other transition metal halides may help to develop alternative synthesis to the high temperature synthesis of transition metal-stannides.

## CHAPTER 2: PHOSPHIDES

BACKGROUND

Since the isolation of the first binary phosphides,  $\text{Li}_3\text{P}$  and  $\text{Na}_3\text{P}$ , by Zintl<sup>40</sup> in 1937, there has been considerable investigation concerning the synthesis and characterisation of the binary species formed by the reaction of phosphorus with group 1 or 2 elements. Similar to the case of polystannides, the first synthetic routes to polyphosphides involved the preparation of alloys of phosphorus and the electropositive metal at high temperatures. Careful control of the conditions during the synthesis of these alloys has led to the isolation of crystalline polyphosphides (Table 2A).

Table 2A Some solvent-free polyphosphides

Compound	Cluster	$p e^-$	ref
$\text{Rb}_3[\text{P}_{7-x}\text{As}_x]$	$\text{P}_{7-x}\text{As}_x^{3-}$	24	41
$\text{M}_4\text{P}_6$ (M=Rb, Cs)	$\text{P}_6^{4-}$	22	42
$\text{Sr}_3\text{P}_{14}$	$2 * \text{P}_7^{3-}$	$2 * 24$	43
$\text{Li}_3\text{P}_7$	$\text{P}_7^{3-}$	24	44

The extraction of these alloys with liquid ammonia yielded mainly solvated phosphides. Destabilisation of the alkali cation upon solvent evaporation resulted in a back electron transfer from

the anions to the alkali metal forming amorphous and highly reactive solids. The use of amine solvents, such as ethylenediamine and TMEDA (tetramethylethylenediamine), or cation sequestering agents, such as 2,2,2-

Figure 2a Structure of the  $\text{P}_7^{3-}$  anion

crypt has enabled the isolation of crystalline species including  $\text{Li}_3(\text{tmeda})_3\text{P}_7^{45}$  (Figure 2a) or  $\text{K}_3(\text{crypt})_3\text{P}_{11}^{46}$ .

The limitations of these high temperature methods became rapidly obvious and include: (i) the inhomogeneous nature of the products which required several annealing/grinding steps and (ii) reactions between the reagents and the container at the temperatures for reaction.

An alternative to the direct reaction of the elements at high temperature was to perform the reactions at lower temperatures in refluxing solvents such as glyme or THF using stoichiometric amounts of soluble white phosphorus ( $\text{P}_4$ ) with metallic sodium or potassium. Using this technique large polyphosphide species such as  $\text{M}_3\text{P}_7$ ,  $\text{M}_2\text{P}_{16}$ ,  $\text{M}_3\text{P}_{19}$ ,  $\text{M}_3\text{P}_{21}$  (M=Na or K) and  $\text{Na}_4\text{P}_{26}$  were synthesised<sup>47,48,49</sup> and their solution structures (Figure 2b) deduced from  $^{31}\text{P}$  NMR studies. These results also revealed the importance of the  $\text{P}_7$  unit in the building of "higher polyphosphides".

**Figure 2b** Structure of some polyphosphides deduced from NMR studies

One of the main problems associated with this synthetic methodology is the lack of selectivity. A mixture of clusters was almost always formed and low yields were common.

A more efficient route to the synthesis of a variety of polyphosphides<sup>50</sup> was offered by the nucleophilic cleavage of white phosphorus with lithium dihydrogenphosphide ( $LiPH_2$ ) (equations 2a and 2b) or the disproportionation of  $Li_2HP_7$ ,<sup>51</sup> (equation 2c). However, the difficulties of handling highly reactive phosphine ( $PH_3$ ) in the preparation of  $LiPH_2$ , together with a lack of selectivity have limited the use of this method.

To date, there is only one reported<sup>52</sup> crystal structure for these high polyphosphides. It was obtained by the oxidation of  $Na_3P_7$  in THF solution in the presence of  $PPh_4Cl$ . The resulting compound had the formula  $(PPh_4)_2P_{16}$  and its solid state structure was similar the one deduced from NMR studies.

Surprisingly, there have been very little investigation of the reactivity of these phosphides. The few reports involved alkylation, silylation or protonation of the heptaphosphide trianion. Table 2B summarizes the results of these reactions.

Table 2B Reactions with  $P_7^{3-}$ 

Starting compound	Reagent	Product	ref
$Li_3P_7$	$Me_3SiCl$	$(Me_3Si)_3P_7$ and $(Me_3Si)_4P_{14}$	53
$(Me_3Si)_3P_7$	MeOH	$H_3P_7$	54
$H_3P_7$	$LiPH_2$	$Li_3P_7$	•
$Li_3P_7$	MeBr	$Me_3P_7$	55

RESEARCH GOALS

1. Investigate the solution synthesis of these polyphosphides starting from white phosphorus and potassium or sodium. This synthetic route may provide a more systematic and efficient approach for their synthesis thus expanding the accessibility of these species for further investigations of their reactivity. It may also allow the synthesis of new polyanions.

2. Explore the features that influence the interconversions between polyphosphides. Carry out "aimed isomerization" reactions.

3. Study the nucleophilic character of these clusters by using them as ligands for transition metal or main group element complexes. This may provide the stabilisation needed in order to prevent decomposition back to the alloy and allow the isolation of new species.

## RESULTS AND DISCUSSION

Our investigation of the synthesis of sodium or potassium phosphides was divided into two approaches. The first approach was to study binary alloys of the alkali metal and phosphorus and their reactivity. The solution synthesis of polyphosphides from potassium and white phosphorus was also examined.

### **Na<sub>3</sub>P: synthesis and extraction**

The simplest binary alloy in the Na/P system, trisodium phosphide (Na<sub>3</sub>P), was prepared by heating stoichiometric amounts of the elements to 500°C for 3 hours. Grinding the powder and annealing it at 500°C for another 12 hours was necessary in order to obtain homogeneous products. Addition of ethylenediamine to Na<sub>3</sub>P resulted in gas evolution together with the formation of a dark orange solution. The gas was trapped using a Toepler pump system and analyzed by M.S. and <sup>1</sup>H NMR (Figure 2c) spectroscopy. From these data, the gas was identified as a mixture of MeNH<sub>2</sub> (major product) and EtNH<sub>2</sub>. The IR spectrum of the yellow solid obtained by evaporation of the ethylenediamine from the orange solution showed a broad band at 3300cm<sup>-1</sup> and a sharp peak at 2380cm<sup>-1</sup> characteristic of P-H groups. The singlet at -273ppm in the <sup>31</sup>P{<sup>1</sup>H} NMR spectra of the orange solution (Figure 2d(a)) can be attributed to NaPH<sub>2</sub><sup>60</sup>. The triplet obtained in the <sup>31</sup>P NMR (Figure 2d(b)) and the doublet (<sup>1</sup>J<sub>P-H</sub>=140Hz) at -1.5ppm in the <sup>1</sup>H NMR spectra of the same solution

Figure 2c <sup>1</sup>H NMR of the gas evolved during the reaction of Na<sub>3</sub>P with ethylenediamine, in benzene-d<sub>6</sub>.

confirm this hypothesis. Similar results were obtained when ethylenediamine was allowed to react with  $K_3P$  and  $KPH_2$  was formed.

This reaction provides an alternative to the use of highly reactive phosphine,  $PH_3$ , for the synthesis of alkali metal dihydrogenphosphides.

#### Reaction of $Na_3P$ with $NbCl_5$

The importance of solid state metathesis reaction in the synthesis of group III-V semi conductors has recently been

demonstrated<sup>4</sup>. A similar synthetic route has also been used for the synthesis of some transition metal nitrides<sup>37</sup>. With these facts in mind, we decided to study the reaction between  $Na_3P$  and  $NbCl_5$ . A mixture containing stoichiometric amounts of  $Na_3P$  and  $NbCl_5$  was heated to 300°C for 12 hours, under vacuum. This procedure yielded a black powder which was then washed with  $H_2O$ ,  $EtOH$  and  $Et_2O$  to remove the  $NaCl$  formed during the reaction and any unreacted starting material. The black powder obtained had a composition of

Figure 2d  $^{31}P$  NMR spectra of  $NaPH_2$ , in ethylenediamine, (a)  $^1H$  decoupled, (b) not  $^1H$  decoupled

$\text{Nb}_3\text{P}_5$  based on XRF analysis and only broad features were observed by powder XRD. This material was thermally stable below  $1000^\circ\text{C}$  when heated under inert atmosphere but decomposed at  $400^\circ\text{C}$  when heated in air.

In an effort to increase the crystallinity of this material and aid in its identification, the powder was annealed at  $600^\circ\text{C}$ , under  $\text{N}_{2(g)}$ , for 12 hours in a quartz tube. During this procedure a small amount of red phosphorus sublimed out of the powder. The powder pattern of the resulting powder as well as the one of the original powder are shown in Figure 2e and compared with literature values for the NbP phase in Table 2C.

Figure 2e Powder pattern of NbP (top) original product (bottom) after annealing

Table 2C Powder XRD data for NbP ( $0^\circ < 2\theta < 60^\circ$ )

literature <sup>36</sup>			experimental			
d (Å)	rel.int. [%]	h	k	l	d (Å)	rel.int. [%]
3.200	60	1	0	1	3.422	33
2.843	30	0	0	4	2.854	24
2.503	55	1	0	3	2.539	27
2.178	100	1	1	2	2.174	100
1.879	30	1	0	5	1.751	21
1.668	25	2	0	0	1.665	24

#### Na/2P alloy: synthesis of $P_7^{3-}$

An alloy of ratio Na/2P was prepared by heating, under  $N_2(g)$ , the elements in stoichiometric amounts to  $300^\circ C$  for 30 minutes. The powder was then ground with a mortar and pestle and extracted with ethylenediamine. The solution was then stirred at room temperature for 12 hours after which a light orange solution was obtained upon filtration. The  $^{31}P$  NMR spectra (Figure 2f) of the orange solution showed a broad singlet at  $-122ppm$ , characteristic of  $P_7^{3-}$  <sup>44</sup>.

#### Ternary alloys: P/Sn/M (M=Na,K)

In an effort to examine the possibility of introducing Sn into one of the phosphide anions, ternary phosphorus/tin/alkali metal alloys were prepared by heating to 300°C for 30 minutes stoichiometric amounts (1:1:1) of the elements. Unlike in the case of binary alloys, the ternary alloys did not look homogeneous and the presence of some metallic tin was observed. Nevertheless, the alloys were ground and extracted with ethylenediamine. Filtration of the resulting solution yielded a dark orange solution. The  $^{31}\text{P}$  solution NMR showed the presence of  $\text{P}_7^{3-}$  and  $\text{MPH}_2$  (M=Na,K) in a 20:3 ratio while no signal was observed between +500 and -1800 ppm in the  $^{119}\text{Sn}$  NMR spectra.

Figure 2f  $^{31}\text{P}$  NMR spectra of the  $\text{P}_7^{3-}$  anion (ethylenediamine solution)

This suggests that the tin is not incorporated during the heating stage and remained unreacted while the sodium and phosphorus react to form the binary alloys  $\text{Na}_3\text{P}$  and  $\text{Na}_2\text{P}$ . The fact that  $\text{NaPH}_2$  or  $\text{KPH}_2$  were not formed during the extraction of the  $\text{Na}_2\text{P}$  alloy may be explained by the presence of excess sodium in the "ternary alloy" which results in the formation of a small quantity of  $\text{Na}_3\text{P}$  or  $\text{K}_3\text{P}$ . This side product then reacts, as previously noted, with the ethylenediamine to form the  $\text{MPH}_2$ .

### Synthesis of $K_2P_{16}$ and $K_3P_{21}$

An alternative to the extraction of binary alkali metal/phosphorus alloys for the preparation of polyphosphides may be offered by reduction of solutions of white phosphorus with alkali metals. The reactions between white phosphorus and metallic potassium were carried out by refluxing, in THF, an 8:1 stoichiometric ratio of the two elements. A dark orange colour started to form within minutes and the reaction was completed in 3 hours. Filtration of the reaction mixture gave a dark orange solution and a dark red solid. The  $^{31}P$  NMR spectra (Figure 2g) of that solution showed the presence of three anions:  $K_2P_{16}$ ,  $K_3P_{19}$  and  $K_3P_{21}$ <sup>48</sup>. Separation of the three anions by crystallisation was not possible.

In an effort to explore alternative solvent systems for the isolation of single polyphosphides, degassed ethanol was used to extract the red solid formed during the reaction described above. All of the solid went into solution to give a dark orange solution for which the  $^{31}P$  NMR spectra (Figure 2h) showed only the  $P_{16}^{2-}$  dianion with a small amount of decomposition products probably due to the presence of residual oxygen. The solution was thermally stable up to the boiling point of ethanol but decomposed readily upon exposure to atmospheric oxygen.

A =  $P_{21}^{3-}$  ( $\delta = +69, +61, -14, -107, -146, -170\text{ppm}$ )  
 B =  $P_{16}^{3-}$  ( $\delta = +61, +43, +5, -39, -134, -170\text{ppm}$ )  
 C =  $P_{19}^{3-}$  ( $\delta = +51, +5, -56, -76, -97, -170, -193\text{ppm}$ )

Figure 2g  $^{31}\text{P}$  NMR spectra of a THF solution of  $P_{16}^{3-}$ ,  $P_{21}^{3-}$  and  $P_{19}^{3-}$

Figure 2g  $^{31}\text{P}$  NMR spectra of a THF solution of  $P_{16}^{3-}$ ,  $P_{21}^{3-}$  and  $P_{19}^{3-}$

Figure 2h  $^{31}\text{P}$  NMR spectra of  $P_{16}^{2-}$  in ethanol

Figure 21  $^{31}P$  NMR spectra of  $P_{213}^{3-}$  in THF

first clear evidence of the interconversion of  $P_{16}^{2-}$  to  $P_{21}^{3-}$ . They also provide a selective and efficient route for the synthesis of these two polyphosphides thus allowing further studies of their reactivity.

**Reaction of  $K_3P_{21}$  with  $R_3ECl$  ( $R=Me, Bu, Ph; E=Si, Sn$ )**

The reactions of  $K_3P_{21}$  with  $R_3ECl$  ( $R=Me, Bu, Ph; E=Si, Sn$ ) were done by stirring, at room temperature, a solution containing stoichiometric amounts of the two components. The results of these reactions are summarised in Table 2D.

**Table 2D Summary of the reaction of  $K_3P_{21}$  with  $R_3ECl$**

$R_3ECl$	reaction time	products
$Me_3SiCl$	<1 minute	insoluble
$Me_3SnCl$	<1 minute	insoluble
$Bu_3SnCl$	12 hours	$P_{16}^{2-}, P_{21}^{3-}, P_{34}^{3-}$ (a)
$Ph_3SnCl$	12 hours	paramagnetic (a)

(a) from  $^{31}P$  NMR studies

The reaction of  $P_{21}^{3-}$  with  $Me_3ECl$  ( $E=Si, Sn$ ) gave only insoluble products making their characterisation difficult. Moving from alkyl substituents to aryl substituents increased the solubility of the

products but the paramagnetism of the products limited the use of  $^{31}\text{P}$  NMR for their characterisation and only broad features were observed (Figure 2k). A low temperature  $^{31}\text{P}$ -NMR experiment was performed and no improvement was observed in the final spectra. The reaction between  $\text{K}_3\text{P}_{21}$  and  $\text{Bu}_3\text{SnCl}$  gave soluble and diamagnetic products. The results of this reaction are discussed in more detail in the next section.

#### Reaction of $\text{K}_3\text{P}_{21}$ with $\text{Bu}_3\text{SnCl}$ : formation of $\text{K}_2\text{P}_{14}$

The reaction of  $\text{K}_3\text{P}_{21}$  with three equivalents of  $\text{Bu}_3\text{SnCl}$  yielded, after filtration through celite, a light orange solution. The  $^{31}\text{P}$  NMR spectra of that solution showed a mixture of clusters and successive precipitation of the THF solution by addition of hexane allowed the isolation of a yellow solid. The  $^{31}\text{P}$  NMR spectra of a THF solution of this solid is presented in Figure 2l. It showed signals at  $\delta = -12, -53, -68, -156$  and  $-172\text{ppm}$  (intensity ratio 1:2:1:2:1) as well as small  $\text{K}_2\text{P}_{16}$  and  $\text{K}_3\text{P}_{21}$  impurities. The number, chemical shifts and intensities of the signals suggests a symmetrical  $\text{P}_7^{3-}$  unit. This hypothesis was confirmed in the 2D- $^{31}\text{P}$  NMR spectrum (COSY) (figure 2m). All  $^1J_{(\text{P-P})}$  couplings of directly linked P atoms appear as cross-peaks. A dimeric structure in which the two  $\text{P}_7^{3-}$  unit can be trans or cis (Figure 2n (a) or (b) respectively) to each other can be proposed. This is the first evidence of the isolated unit  $\text{K}_2\text{P}_{14}$ . It is also the first example of the oxidative coupling of two  $\text{P}_7^{3-}$  unit.

Figure 2k  $^{31}\text{P}$  NMR spectra of the products of the reaction between  $\text{K}_3\text{P}_2$  and  $\text{Ph}_3\text{SnCl}$

Figure 21  $^{31}\text{P}$  NMR spectra of  $\text{K}_3\text{P}_{14}$  in THF solution

Figure 2m 2D- $^{31}\text{P}$  NMR spectrum of the  $\text{P}_7\text{-1-}$  skeleton (256\*256 matrix)

Other reactions attempted with  $P_{21}^{3-}$  include the reactions with inorganic halides, such as  $AlCl_3 \cdot 3thf$  and  $Cp_2ZrCl_2$ . The products of these reactions were not fully characterised and will not be discussed here.

Figure 2a Possible structures of  $K_2P_{14}$ , (a) trans (b) cis

CONCLUSIONS

The availability of pure polyphosphides has, until this work, limited the study of their reactivity. However, the interconversion of  $P_{16}^{2-}$  to  $P_{21}^{3-}$  provides a new synthetic route to "clean" polyphosphides thus allowing further characterisation of their chemical behaviour. Controlled oxidation or metathesis reactions using inorganic halides represent the next frontier in this field. Their use as ligands in organometallic complexes may result in new species with unusual properties based on the interaction of the metal centre with the polyphosphides ligand system.

**EXPERIMENTAL****GENERAL**

N.B. Unless otherwise specified, the purification of the starting materials and the reactions were performed in the absence of air and water using standard Schlenk techniques.

**Purification of starting materials:*****The solvents***

Tetrahydrofuran, hexanes, diethyl ether, pyridine, 1,2-dimethoxyethane, toluene and ethylenediamine were dried by reflux over Na/K alloy for 10 to 12 hours. In the other cases, P<sub>2</sub>O<sub>5</sub> (methylene chloride, carbon tetrachloride), CaH<sub>2</sub> (ethanol, methanol) or molecular sieves (dimethyl formamide) were used depending on the solvent.

***The elements***

Lithium (Aldrich, 99+%), sodium (Strem, ACS) and potassium (Strem, 99.99%) metals were washed with hexanes in order to remove the protective oil then dried under vacuum. The white (Aldrich, 99+%) and red (Strem, 99.99%) phosphorus allotropes, the metallic tin (powder and shots) (Aldrich, 99.99%) and the sulphur (yellow) (Aldrich, sublimed) were used as received.

### *The organic cations*

Tetramethyl ammonium chloride ( $\text{Me}_4\text{NCl}$ ), Tetrabutyl ammonium chloride ( $\text{Bu}_4\text{NCl}$ ), Tetraphenyl phosphonium bromide ( $\text{Ph}_4\text{PBr}$ ) and Benzyltriethyl ammonium chloride ( $\text{BzEt}_3\text{NCl}$ ) were dissolved in ethanol and precipitated by the addition of diethyl ether. After filtration and drying under vacuum, infrared spectroscopy was used to verify the absence of residual water or ethanol in the solid.

Benzyltrimethyl ammonium chloride ( $\text{BzMe}_3\text{NCl}$ ) was synthesised in quantitative yield by refluxing  $\text{Me}_3\text{N}$  and  $\text{BzCl}$  in toluene overnight followed by recrystallisation from ethanol/ether.

Bis(triphenyl phosphonium) ammonium chloride ( $\text{PPNCl}$ ) was synthesized using a previously reported method<sup>57</sup>.

### *The organic halides*

Trimethyl silyl chloride ( $\text{TMSCl}$ ), Benzyl bromide ( $\text{BzBr}$ ) and Phenyl bromide ( $\text{PhBr}$ ) were dried using  $\text{P}_2\text{O}_5$  followed by distillation. The purity of the distillate was monitored with  $^1\text{H}$  NMR.

Triphenyl tin chloride ( $\text{Ph}_3\text{SnCl}$ ) was purified by recrystallisation from THF and then dried under vacuum for 10 to 12 hours.

Trimethyl tin chloride ( $\text{Me}_3\text{SnCl}$ ) and Tributyl tin chloride ( $\text{Bu}_3\text{SnCl}$ ) were used as received from Aldrich.

#### *The inorganic halides*

Niobium pentchloride ( $\text{NbCl}_5$ ) was purified through sublimation under vacuum.

Bis(cyclopentadienyl) zirconium dichloride ( $\text{Cp}_2\text{ZrCl}_2$ ) was used as received.

#### **Instrumentation**

##### *NMR spectroscopy*

The  $^1\text{H}$  NMR experiments were performed on a Varian Gemini 200 XL while the other nuclei  $^{13}\text{C}$ ,  $^{31}\text{P}$  and  $^{119}\text{Sn}$  were studied using a 300 MHz Varian spectrometer. The spectrometer frequency was set respectively to 75.43MHz, 121.42MHz, 111.75 MHz.

All  $^1\text{H}$  NMR spectra were referenced to residual protons of the solvent. Solvent signals were also used as reference for the  $^{13}\text{C}$  NMR spectra. 10%  $\text{H}_3\text{PO}_4$  in  $\text{H}_2\text{O}$  and  $\text{Me}_4\text{Sn}$  or  $\text{Na}_4\text{Sn}$ ,<sup>d</sup> were used as external reference for the  $^{31}\text{P}$  and  $^{119}\text{Sn}$  NMR.

---

<sup>d</sup>  $\text{Me}_4\text{Sn}$  was used for signals between  $\delta=800$  and  $-800\text{ppm}$   
 $\text{Na}_4\text{Sn}$ , was used for the more upfield signals

### *FTIR spectroscopy*

Most IR spectra were recorded using Nujol mull between NaCl plates. Both Mattson 3000 and Bomem Michelson series 100 FTIR systems were used.

### *Thermal Analysis*

A polymer laboratories simultaneous DSC/TGA STA1500H (Differential Scanning Calorimetry/ThermoGravimetric Analysis) was used for all thermal analysis. A heating rate of 10°C/min was found to be ideal for both speed and quality purposes. Measurements on air sensitive samples were done in sealed aluminium pans while the air stable samples were measured in an alumina pan. In both case, the samples were heated under  $N_2(g)$  at a flow rates of 40-60  $cm^3/s$ .

### *P-XRD (Powder X-Ray Diffraction)*

The instruments used was a Phillips PW3710 based Xpert system. The powder patterns for the air sensitive samples were analysed using a brass air tight holder while the stable samples were done using a no background rotating Si holder. In both case the samples were collected using  $Cu_{K\alpha}$  radiations (wavelength 1.54060).

## REACTIONS

### **Synthesis of $Na_3Sn$ ,**

Na/Sn alloys of composition varying from 1/3 (tin rich) to 3/1 (sodium rich) were prepared by heating the elements to 300°C for 30

minutes under  $N_{2(g)}$ . The alloy was then ground with a mortar and pestle and extracted with ethylenediamine. The resulting suspension was then filtered to give a dark red solution.

The  $^{119}\text{Sn}$  NMR of these solutions showed a pseudo quintet at  $\delta = -1230\text{ppm}$  with  $J_{\text{Sn}117-\text{Sn}119} = 258\text{Hz}$ . This signal was attributed to  $\text{Na}_4\text{Sn}9^{28}$ .

Due to the extreme sensitivity of the solution toward oxidation, attempts to isolate the compound in the solid state were unsuccessful.

#### Synthesis of $\text{Na}_4\text{Sn}$

In a typical reaction, metallic sodium (1.75g; 76mmol) was heated under  $N_{2(g)}$  in the presence of tin metal (2.25g; 19mmol) to 300 °C for about 30 minutes. Upon cooling, a grey crystalline material is obtained in quantitative yield.

The IR spectrum of the compound showed no observable absorption band between  $\nu = 4000 - 500\text{ cm}^{-1}$ . Thermal analysis (DSC) showed only one reversible thermal event at 407 °C which can be assigned to the melting of the compound. The homogeneity of the compound was demonstrated by comparison of the experimental powder pattern with the calculated one.

#### Crystal structure of $\text{Na}_4\text{Sn}$

### Data collection

A crystal of  $\text{Na}_2\text{Sn}$  having approximate dimensions of  $0.4 \times 0.3 \times 0.3 \text{ mm}$  was mounted on a glass capillary. All the measurements were made using a Rigaku diffractometer with  $\text{MoK}\alpha$  radiation.

Cell constants and an orientation matrix for data collection obtained from least-squares refinement using the setting angles of 25 reflections in the range  $30 < 2\theta < 50$  corresponded to an orthorhombic cell with dimensions:

$$a = 9.744(3)$$

$$b = 22.751(10)$$

$$c = 5.5390(15)$$

For  $Z = 8$  and  $\text{FW} = 210.65$ , the calculated density is  $2.279 \text{ g/cm}^3$ . Based on the systematic absences, the space group was determined to be  $\text{Pnam}$ .

The data were collected at a temperature of  $-110 \text{ }^\circ\text{C}$  using omega-2theta scan technique to a maximum  $2\theta$  value of  $49.9$  degrees.

### Data reduction

A total of 1202 reflections were collected. The unique set contains only 1202 reflections. The standards were measured after every 150 reflections. No crystal decay was noticed. The data were corrected for Lorentz and polarisation effects<sup>58</sup>. Absorption

correction was made. The minimum and maximum transmission factors are 0.06096, 0.08103.

#### *Solution and refinement*

The structure was solved by direct methods. All the atoms were refined anisotropically. The final cycle of full matrix least-squares refinement was based on 1052 observed reflections ( $I > 2.5 \sigma(I)$ ) and 62 variable parameters. Weights based on counting statistics were used. The maximum and minimum peaks on the final difference Fourier map corresponded to 2.550 and -3.950 respectively, showing residual around the two tin atoms.

All calculations were performed using the NRCVAX crystallographic software package<sup>59</sup>.

N.B. To produce the plots, the space group was transformed from Pnam to Pnma (#62) using the following transformation matrix.

$$\begin{vmatrix} 1 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{vmatrix}$$

### Reactions of $\text{Na}_4\text{Sn}$ with organic cations

#### Reaction of $\text{Na}_4\text{Sn}$ with $\text{Ph}_4\text{PBr}$

0.11g of  $\text{Na}_4\text{Sn}$  (0.5 mmol) was stirred at room temperature with 0.89g of  $\text{Ph}_4\text{PBr}$  (2.1 mmol) in THF. Within 1 hour, the solution turned dark orange and a grey precipitate formed (0.26g; 94 % of  $\text{NaBr} + \text{Sn}$ ). Evaporation of the solvent yielded a dark orange oil.

$^1\text{H}$  NMR (in THF) (m)  $\delta=7.25\text{ppm}$  (m),  $\delta=7.61\text{ppm}$  (m) and  $\delta=7.8\text{ppm}$  (Ph's  $^1\text{H}$ );  $^{31}\text{P}$  (s)  $\delta=-85.1\text{ppm}$  ( $\text{PPh}_3$ ), (s)  $\delta=-4.8\text{ppm}$  ( $\text{PPh}_3$ ); IR  $\nu=1070$  and  $701\text{ cm}^{-1}$  indicative of aromatic rings.

The pentaphenyl phosphine was isolated by recrystallisation in toluene and then thoroughly characterised through DSC/TGA and X-Ray crystallography.

#### Reaction of $\text{Na}_4\text{Sn}$ with Bis(triphenylphosphine) ammonium chloride ( $\text{PPNCl}$ )

$\text{Na}_4\text{Sn}$  (0.08g;0.4mmol) and  $\text{PPNCl}$  (0.92g;1.6mmol) were left to react at room temperature in THF for 2 hours. A dark orange solution was obtained together with a white precipitate. An oily liquid was obtained upon evaporation of the solvent.

The  $^1\text{H}$  NMR spectra of this liquid showed three aromatic multiplets at  $\delta=6.95\text{ppm}$ ,  $7.45\text{ppm}$  and  $7.70\text{ppm}$ . The  $^{31}\text{P}$  NMR spectra was quite complex and only  $\text{PPh}_3$  ( $\delta=-4.8\text{ppm}$ ) was identified. Attempts to purify this mixture by recrystallisation using a variety solvents (such as THF, DME, hexanes and diethyl ether) were unsuccessful.

#### Reaction of $\text{Na}_4\text{Sn}$ with $\text{BzEt}_3\text{NCl}$

$\text{Na}_4\text{Sn}$  (0.19g;0.9mmol) reacts within minutes with  $\text{BzEt}_3\text{NCl}$  (0.81g;3.6mmol) in both THF or diethyl ether to give a dark orange solution and a grey precipitate ( $\text{Sn}(0) + \text{NaCl}$ ). An orange oil is obtained upon evaporation of the solvent.

$^1\text{H}$  NMR **A**  $\delta=0.98$  ppm(dt) ( $J_d=16.9\text{Hz}$ ,  $J_t=7.6\text{Hz}$ ); **B**  $1.85$  ppm(q) ( $J_q=7.6\text{Hz}$ ); **C**  $\delta=2.15$  ppm(dd) ( $J_d=19.8\text{Hz}$ ,  $J_d=6.8\text{Hz}$ ); **D**  $\delta=7.05\text{ppm}$ (m); **E**  $\delta=7.48$  ppm(m); **F**  $\delta=7.68$  ppm(m).

Successive sublimations under vacuum of this oil yielded a viscous liquid for which the signal noted as **C** did not appear.

If the same reaction is done in benzene at reflux temperature, a colorless solution is obtained. The  $^1\text{H}$  NMR spectra of this solution showed the three aromatic signals (D, E & F) and the benzylic  $\text{CH}_2$ 's protons (C).

#### *Reaction of $\text{Na}_4\text{Sn}$ with $\text{Me}_4\text{NCl}$ , $\text{Bu}_4\text{NBr}$ , $\text{BzMe}_3\text{NCl}$*

THF suspensions of  $\text{Na}_4\text{Sn}$  and 4 equivalents of the ammonium salts were refluxed overnight without any reaction.

#### *Reactions of $\text{Na}_4\text{Sn}$ with organic halides*

##### *Reaction of $\text{Na}_4\text{Sn}$ with $\text{Me}_3\text{SiCl}$ , $\text{Ph}_3\text{SnCl}$ , $\text{PhCl}$ , $\text{BzBr}$ and $\text{CCl}_4$*

In these five cases, the organic halide and the  $\text{Na}_4\text{Sn}$  were suspended in THF in a ratio 4 to 1. The suspension was then refluxed for 2 hours without any results.

#### *Reactions of $\text{Na}_4\text{Sn}$ with inorganic halides*

N.B. Special care should be taken when reacting  $\text{Na}_4\text{Sn}$  with inorganic halides ( $\text{NbCl}_5$ ) or elements (P and S). The reactions between the two powders are violent and highly exothermic.

##### *Reaction of $\text{Na}_4\text{Sn}$ with $\text{NbCl}_5$*

Fifteen equivalents of  $\text{Na}_4\text{Sn}$  (0.59g; 2.8mmol) were mixed with 8 equivalents of  $\text{NbCl}_5$  (0.41g; 1.5mmol). The reaction mixture was then heated to 110 °C for 12 hours inside a TEFLON lined acid

digestion bomb. Washing the solid with H<sub>2</sub>O, EtOH and then Et<sub>2</sub>O gave a black powder of composition Nb<sub>7</sub>Sn<sub>2</sub>, based on X-Ray fluorescence elemental analysis, which still contained two NaCl equivalents. The DSC done under inert atmosphere showed no thermal event before 1100°C while the one done under compressed air atmosphere showed a broad exothermic event at 500°C together with a weight increase of about 6%. The IR spectrum showed no bands and the amorphous nature of the compound was confirmed by Powder XRD.

#### Reaction of Na<sub>4</sub>Sn with GaCl<sub>3</sub> or AlCl<sub>3</sub>

Typically Na<sub>4</sub>Sn (0.47g; 2.2mmol) was heated with 3.0mmol of the halides (0.40g for AlCl<sub>3</sub>; 0.53g for GaCl<sub>3</sub>) 400°C in a sealed glass tube for 10 hours.

DSC studies allowed the identification of metallic tin as one of the products.

#### Reactions of Na<sub>4</sub>Sn with elements

##### Reaction of Na<sub>4</sub>Sn with elemental phosphorus

##### Red phosphorus

One equivalent of Na<sub>4</sub>Sn (0.23g; 1.1mmol) was heated, for 12 hours, to 200°C in a sealed glass tube with 2/3 equivalent of red phosphorus (0.02g; 0.7mmol).

White phosphorus

$\text{Na}_4\text{Sn}$  (0.23g; 1.1mmol) and white phosphorus (0.02g; 0.7mmol) were heated under reflux in toluene for 12 hours.

Both procedures gave a black solid which was then extracted with ethylenediamine. The addition of ethylenediamine resulted in a gas evolution accompanied by the formation of an orange solution. NMR, M.S. and IR spectroscopy showed the presence of  $\text{MeNH}_2$ ,  $\text{EtNH}_2$ ,  $\text{NaPH}_2$  and  $\text{Na}_4\text{Sn}_9$ . Toepler pump experiment showed that 1.3 mmoles of gas were evolved starting with 0.1g of the powder.

$^1\text{H}$  NMR ( $\delta=0.65\text{ppm}(\text{bs})$  (-NH),  $\delta=1.95\text{ppm}(\text{t})$  (Et's  $\text{CH}_3$ ),  $\delta=2.19\text{ppm}(\text{s})$  (Me's  $\text{CH}_3$ ),  $\delta=2.6\text{ppm}(\text{q})$  ( $\text{CH}_2$ ))

$^{31}\text{P}$  NMR ( $\delta=-275.2\text{ppm}(\text{t})$ ;  $^1J_{\text{H-P}}=140\text{Hz}$ ) and  $^{119}\text{Sn}$  NMR ( $\delta=-1230\text{ppm}(\text{p})$ ;  $J_{\text{Sn}117-\text{Sn}119}=258\text{Hz}$ ), IR ( $\nu=3300$  and  $2380\text{cm}^{-1}$  (P-H)).

Reaction of  $\text{Na}_4\text{Sn}$  with elemental sulfur

Typically,  $\text{Na}_4\text{Sn}$  (0.77g; 3.7mmol) and S (0.23g; 7.2mmol) were sealed under vacuum in a glass tube and then heated to  $300^\circ\text{C}$  for 30 min after which heterogeneous looking solids were obtained.

Synthesis of  $\text{Na}_3\text{P}$  and  $\text{K}_3\text{P}$ 

A modification of a previously reported method<sup>40</sup> was used for the synthesis of  $\text{Na}_3\text{P}$ . Sodium (1.38g; 60.0mmol) and red phosphorus (0.62g; 20.0mmol) were heated under  $\text{N}_2(\text{g})$  to  $500^\circ\text{C}$  for 3 hours. The

tube was then cooled and the solid grounded with a mortar and pestle. The powder was then annealed at 500°C for 10 hours to form a black homogeneous powder. A similar procedure was used to prepare  $K_3P$  starting with potassium (1.58g;40.4mmol) and red phosphorus (0.42g;13.5mmol).

#### Reaction $Na_3P$ with $NbCl_5$

$Na_3P$  (0.48g;4.8mmol) and  $NbCl_5$  (0.52g;1.9mmol) were heated under vacuum to 300°C for 12 hours. The product was then washed with water, ethanol and diethyl ether to remove any unreacted starting material and the  $NaCl$  formed during the reaction. The black powder obtained by this procedure was then grounded with an agate mortar and pestle and annealed in a quartz tube at 600°C under dynamic nitrogen for 12 hours. The powder pattern of the resulting solid showed an increased crystallinity compared to the non-annealed material.

d-value (Å) (relative intensity): 3.42(33); 2.85(24); 2.54(27); 2.42(6); 2.17(100); 1.75(21); 1.71(8); 1.67(24).

#### Preparation of $NaPH_2$ and $KPH_2$

Extraction of  $Na_3P$  (2.0g;20.0mmol) with ethylenediamine resulted in gas formation together with coloration of the solution. Evaporation of the ethylenediamine gave a yellow solid which was very soluble in ethylenediamine and pyridine, slightly soluble in THF and insoluble in diethyl ether or hexanes. The  $^{31}P$  ( $^1H$ ) NMR

spectra of the ethylenediamine solution showed a singlet at  $\delta = -273.2$  ppm while the  $^1\text{H}$  coupled spectra showed a triplet with  $^1J_{\text{H-P}} = 140$  Hz. The  $^1\text{H}$  NMR spectra of the same solution showed a doublet at  $-1.5$  ppm ( $^1J_{\text{H-P}} = 140$  Hz). The IR spectra showed bands at  $\nu = 3300$  (b) and  $2380$  (s)  $\text{cm}^{-1}$  which are characteristic of  $\text{NaPH}_2$ <sup>60</sup>.

$^1\text{H}$  NMR of the gas evolved during the reaction showed a broad peak at  $0.65$  ppm (NH), a triplet and a quartet at respectively  $0.98$  ppm and  $2.6$  ppm (Et's) and a singlet at  $2.35$  ppm (Me's).

Similar reactivity was observed with  $\text{K}_3\text{P}$  to form  $\text{KPH}_2$ .

#### Synthesis of Na/2P alloy and extraction to yield $\text{P}_7^{3-}$

Sodium ( $0.27$  g;  $11.7$  mmol) and red phosphorus ( $0.73$  g;  $23.4$  mmol) were heated to  $400$  °C under  $\text{N}_2(\text{g})$  for 30 minutes. The red-brown solid obtained from this reaction was then extracted with 25 ml of ethylenediamine resulting in the formation of a light orange solution.  $^{31}\text{P}$  NMR showed a broad signal at  $\delta = -122.1$  ppm characteristic of  $\text{P}_7^{3-}$  in solution.

#### Synthesis of M/Sn/P (M=Na,K) alloys

Potassium ( $0.15$  g;  $3.8$  mmol) or sodium ( $0.09$  g;  $3.9$  mmol), tin ( $0.45$  g;  $3.8$  mmol) and red phosphorus ( $0.11$  g;  $3.6$  mmol) were heated to  $400$  °C under  $\text{N}_2(\text{g})$  for 30 minutes. The solid obtained appeared to be heterogeneous and metallic tin was present.

The  $^{31}\text{P}$  NMR spectra of the solution formed by the extraction of that solid with ethylenediamine showed a broad singlet at  $\delta = -122.1$  ppm and a triplet at  $\delta = -273.1$  ppm ( $J = 140\text{Hz}$ ). The first signal has been attributed to  $\text{P}_7^{3-}$  and the second to  $\text{MPH}_2$ . Integration of the two signals showed that the solution contained 20  $\text{P}_7^{3-}$  moiety for every 3  $\text{NaPH}_2$ . The  $^{119}\text{Sn}$  NMR spectra contained no signals between +1000 and -2000 ppm.

#### Synthesis of $\text{K}_2\text{P}_{16}$ , $\text{K}_3\text{P}_{18}$ and $\text{K}_3\text{P}_{21}$

White phosphorus (0.86g; 27.8mmol) was refluxed with potassium (0.14g; 3.6mmol) in THF/DME (1:1) for 3 hours. The solvent was then removed under vacuum to form a deep red solid. This technique allowed the recovery of 1.00g of crystalline  $\text{K}_2\text{P}_{16}$  solid starting from a total of 1.00 grams of material (100% yield).

The  $^{31}\text{P}$  NMR of the orange solution obtained by extraction of the solid with degassed ethanol only showed the presence of  $\text{K}_2\text{P}_{16}$ . The solution was stable to solvolysis but decomposed rapidly to phosphoric acid when exposed to atmospheric oxygen. A red solid was obtained by vacuum evaporation of the solvent. The IR spectrum of the red solid sometimes showed bands at  $\nu = 2700, 1200, 1140$  and  $830\text{ cm}^{-1}$  which are characteristic of DME.

#### Reaction of $\text{K}_3\text{P}_{21}$ with $\text{Ph}_3\text{SnCl}$

A small excess of  $\text{Ph}_3\text{SnCl}$  (0.37g; 1.0mmol) was added to a THF solution of  $\text{K}_3\text{P}_{21}$  (0.20g; 0.3mmol) and stirred at room temperature

for 12 hours to yield a white solid and a bright yellow solution. The solid was then removed by filtration. Addition of hexanes to the THF solution resulted in the precipitation of a yellow solid (0,08g) which was soluble in toluene, pyridine and DME.  $^{31}\text{P}$  NMR of the toluene solution showed the presence of paramagnetism.

#### Reaction of $\text{K}_3\text{P}_{21}$ with $\text{Me}_3\text{SiCl}$

The  $\text{Me}_3\text{SiCl}$  (10ml;79.0mmol) was added in excess to a THF solution of  $\text{K}_3\text{P}_{21}$ (0.41g;0.5mmol). Immediate precipitation was observed leaving the solution nearly colorless. Attempts to extract the reaction products from the precipitate with a variety of solvent (THF, DME, Toluene,  $\text{Et}_2\text{O}$ , hexanes) were unsuccessful.

#### Reaction of $\text{K}_3\text{P}_{21}$ with $\text{Me}_3\text{SnCl}$

The  $\text{Me}_3\text{SnCl}$  (0.41g;2.1mmol) was added to a THF solution of  $\text{K}_3\text{P}_{21}$  (0.41g;2.1mmol) causing the immediate precipitation of a yellowish insoluble solid.

#### Reaction of $\text{K}_3\text{P}_{21}$ with $n\text{Bu}_3\text{SnCl}$

To a THF solution of  $\text{K}_3\text{P}_{21}$  (0.40g;0.5mmol) was added (0.50g;1.6mmol) of  $n\text{Bu}_3\text{SnCl}$ . The solution was then allowed to stir at room temperature for 12 hours after which a cloudy light orange solution was obtained. Filtration of the solution over celite followed by evaporation of the solvent yielded a light brown solid which was then purified by several precipitation via addition of hexane to THF solutions. The brown solid obtained (0.36g) (88%

yield calculated for the formula  $(KP_7)_n$  did not contain tin based on XRF. The  $^{31}P$  NMR spectra of a THF solution of that solid showed signals at  $\delta = -12, -53, -68, -156$  and  $-172$  ppm in a ratio 1:2:1:2:1 as well as  $K_2P_{16}$  and  $K_3P_{21}$  impurities.

#### Reaction of $K_3P_{21}$ with $Cp_2ZrCl_2$ (Cp=cyclopentadienyl)

$K_3P_{21}$  (0.60g; 0.8mmol) was stirred in THF with  $Cp_2ZrCl_2$  (0.38g; 1.3mmol) for 12 hours. The solution was then filtered over celite to give a red solution and a pale solid. The  $^{31}P$  NMR was characteristic of mixture of  $K_2P_{16}$  and  $K_3P_{21}$ . The  $^{13}C$  ( $^1H$ ) NMR showed one signals at  $\delta = 106$ ppm and a singlet at 5.81ppm was found in the  $^1H$  NMR. Both signals are upfield to the Cp signal in  $Cp_2ZrCl_2$ ,  $^{13}C$   $\delta = 116.2$ ppm,  $^1H$   $\delta = 6.48$ ppm.

#### Reaction of $K_3P_{21}$ with $AlCl_3 \cdot 3thf$

A THF solution of  $AlCl_3 \cdot 3thf$  (0.50g; 1.4mmol) was added slowly to a THF solution of  $K_3P_{21}$  (0.30g; 0.4mmol). Immediate precipitation of a yellowish material was observed. Due the presence of KCl in the solid and its insolubility, no characterisation was done on this product.

## CLAIMS TO ORIGINAL RESEARCH

1.  $\text{Na}_4\text{Sn}$  can be synthesised by solid state reaction starting from stoichiometric of the elements. It crystallizes in the orthorhombic space group  $\text{Pnam}$  with a unit cell of dimensions  $a=9.744(3)\text{\AA}$ ,  $b=22.751(10)\text{\AA}$ ,  $c=5,5390(15)\text{\AA}$ . The most striking features are the two different tin environments and the lack of Sn-Sn interactions.
2. The reactivity of  $\text{Na}_4\text{Sn}$  with organic and inorganic halides, elements and organic cations was investigated.
3.  $\text{MPH}_2$  ( $M=\text{Na},\text{K}$ ) is synthesised by the reaction between  $\text{M}_3\text{P}$  and ethylenediamine. This can be used as an alternative route to the use of highly reactive phosphide,  $\text{PH}_3$ , for the synthesis of alkali metal dihydrogenphosphides.
4. The first clear evidence of the interconversion between  $\text{P}_{21}^{3-}$  and  $\text{P}_{16}^{2-}$  was demonstrated. The importance of the solvent on this interconversion was also shown.
5. This reaction provides a selective and high yield synthetic route to these two polyphosphides thus allowing further studies of there reactivity.
6. The oxidation of  $\text{P}_{21}^{3-}$  in the presence of  $\text{Bu}_3\text{SnCl}$  yields the new polyphosphide:  $\text{P}_{14}^{2-}$ .
