Control of Self-Organizing and Geometric Formations

Navigation and Formation Control Methods using the Velocity Potential Flow and the Reconfiguring Leader-Follower Controller

Abstract

Multi-vehicle systems offer many advantages in engineering applications such as increased efficiency and robustness. However, the disadvantage of multi-vehicle systems is that they require a high level of organization and coordination in order to successfully complete a task. Formation control is a field of engineering that addresses this issue, and provides coordination schemes to successfully implement multi-vehicle systems. Two approaches to group coordination were proposed in this work: geometric and self-organizing formations. A geometric reconfiguring formation was developed using the leader-follower method, and the self-organizing formation was developed using the velocity potential equations from fluid flow theory. Both formation controllers were first tested in simulation in MATLAB, and then implemented on the X80 mobile robot units. Various experiments were conducted to test the formations under difficult obstacle scenarios. The robots successfully navigated through the obstacles as a coordinated as a team using the self-organizing and geometric formation control approaches.

Dedication

This work is dedicated to my family and friends, without whom this work would not have been possible. I would like to specifically thank my parents for their ongoing support, and to Shaz, for his love and encouragement through this journey of mine.

Acknowledgements

I would like to express my gratitude and thanks to my supervisor Dr. Dan Necsulescu. We have worked together for many years now, and you have given me the time, support, patience, and guidance to let me flourish under your supervision. I would also like to thank Dr. Bumsoo Kim who facilitated the research work with Defense Research and Development Canada (DRDC), and provided the X80 mobile robots for our formation experiments. Finally, I would like to thank my colleagues in the research lab for their ideas, encouragement, and advice. I will always remember the long nights working on robot experiments, thank you Sharareh, Ehsan, and Mostafa.

Chapter 1

Introduction

1.1 Motivation

There is currently a strong motivation to implement autonomous robot systems in military, civilian, and commercial applications. Over the past decade, unmanned vehicle systems have become increasingly prevalent in the military settings; this is primarily due to their reconnaissance, and surveillance abilities. Enhanced intelligence through robotic systems allow military leaders to make better, more informed decisions, which in turn has saved countless lives on the battlefield. Furthermore, civilian applications are also greatly enhanced by autonomous robotic systems. Organizations such as police, emergency response, coast guard, fire response, search and rescue, border security, and arctic surveillance all implement unmanned robotic systems, and these unmanned vehicles allow first responders to stay a safe distance away from dangerous situations. Finally, autonomous robots will play a large role in emerging commercial applications in natural resources sectors such as mining, oil and gas, and agriculture; moreover, they will continue to increase efficiencies in manufacturing, warehousing, and distribution.

At present, there is a great interest in deploying multi-robot systems in military, civilian, and commercial applications. Multi-robot systems have many benefits over their single robot counterparts, since they can perform tasks with greater efficiency, less cost, and they present a more robust solution. Autonomy and group coordination are key traits for the successful navigation of robot teams in dynamic environments. Autonomous motion in multi-robot systems is a very complex problem, and scientists and engineers from different fields are working together to come up with solutions.

Most navigation solutions for autonomous mobile robots are designed for single robot systems. Multi-robot systems are more complex than their single robot counterparts, and require extra elements such as networked communication and group coordination strategies, to perform their tasks effectively. Teams of mobile robots must decide as a group what is the best path of motion when difficult obstacles configurations appear in the environment. There is still no perfect solution to the multi-robot coordination problem, and researchers are currently publishing new and innovative solutions. Solving the navigation and coordination problems for multi-robot systems could change the way many robot systems are used in military, civilian, and commercial applications. Multi-agent robotic systems are a billion dollar industry, and researchers and corporations are racing to develop the best technologies.

1.2 Research Objective

In order to increase the productivity of multi-robot systems, and to avoid inter-robot collisions during their mission, it is very important to develop a coordination strategy among members of the team. Coordination strategies for multi-robot systems define how a group of homogeneous robots travel through a terrain without collid-

ing into obstacles or other robots along their paths. In our research we will look at two strategies for coordination: self-organizing and geometric formations. We will also develop a navigation strategy to move the formation through the terrain to a goal position without colliding with static obstacles in the environment. We will be developing controllers to allow for the decentralized autonomous movement of the team. Controllers will use sensor information to update feedback control systems for each robot. A central controller will be responsible for overall group formation decisions such as formation shape and separation distance between the robots, while individual robots will make reactive decentralized decisions on the best movement that goes along with the team formation objectives. Controllers will first be tested on a group of simulated robots, and then the controllers will be applied in experimentation with a group of differential drive lab robots.

1.3 Method of Approach

Two types of formations will be examined in this work. Firstly, a geometric formation will be developed using a reconfiguring Leader-Follower controller. In this formation, the leader will navigate autonomously through the terrain, while the followers will orient themselves at predefined positions behind the leader. The leader-follower geometric formation will add order and organization to the group as they travel through the environment. Secondly, a self-organizing formation will be developed using the velocity potential flow method. In this method, the velocity potential model will regulate local interaction between the vehicles, and the vehicles will organize themselves in a self-organized formation, in order to avoid inter-robot collisions as the team travels towards the goal position.

1.4 Thesis Outline

This work consists of eleven chapters that go through the process of designing and executing formation controllers for a team of mobile robots.

Chapter 2 provides background information about autonomous mobile robots, motion planning, navigation, and formation control for multi-vehicle systems.

Chapter 3 provides a literature review that examines formation control strategies in literature, and an analysis of each method is carried out.

Chapter 4 describes the proposed navigation and formation control approaches, and derives the equations of motion for the differential drive vehicles.

Chapter 5 details the hardware components on the X80 mobile robot that is used in our experiments. This chapter examines the sensors, actuators, and processing that allows the X80 robot to travel autonomously through the terrain.

Chapter 6 describes the hardware-software interaction, and how high-level navigation controllers are sent to the X80 robot through a wireless network.

Chapter 7 describes the simulation and experimental design in MATLAB and Player/Stage. This chapter details the steps needed to execute formation controllers on simulated robots and on the X80 robots.

Chapter 8 is the first results chapter, and explains the simulation and experimental work for single robot navigation.

Chapter 9 is the second results chapter, and describes the simulation and experimental work in developing geometric formation controllers.

Chapter 10 is the final results chapter, and describes the simulation and experimental work in developing self-organizing formation controllers.

Finally, Chapter 11 provides a conclusion to this work, explains our research contributions, and discusses future work in this project.

Chapter 2

Background Information

2.1 Mobile Robots

Mobile robots are currently at the forefront of research and innovation. They are designed to search and explore large areas, to perform repetitive, unpleasant, or dangerous tasks, and are engineered to work in unstructured and dynamic environments. Mobile robots are used in tasks such as agriculture, container handling, intelligent transportation, inspection, scientific exploration, mining, waste management, search and rescue, fire-fighting, and military applications[4]. There is a great interest in the research and deployment of mobile robots, since they can reduce the cost of operations, and perform tasks with greater speed and efficiency than humans[17].

There are many types of mobile robots in use today, and their classification is based on their working environments. Mobile robots working on land are called Unmanned Ground Vehicles (UGV), mobile robots working underwater are called Autonomous Underwater Vehicles (AUV), and mobile robots working in the air are called Unmanned Aerial Vehicles (UAV). Within the three sub-genres, robots can be further classified based on their mechanisms for locomotion. For example,

wheels or legs generally power unmanned ground vehicles, and the design choices are made based on the needs of the operating environment. Legged mobile robots have the advantage of being more maneuverable and adaptable in rough terrain, and generally mimic legged configurations of animals in nature. Mobile robots with legs incur high degrees of freedom, they tend to be mechanically complex, and are expensive to build and manufacture. For the vast majority of applications, wheeled mobile robots are preferred since they are mechanically simpler, they can travel at high velocities, and suspension systems can be added to handle many types of terrain[53]. Furthermore, autonomous underwater vehicles can be further classified into submarines or biologically inspired vehicles that mimic the movement of sea creatures. Finally, unmanned aerial vehicles are further classified by their wing design and are either fixed wing or rotary wing. Fixed wing UAVs are used for applications that require traveling long distances, and rotary winged aircraft, like the quad-rotor aircraft, are implemented in applications that require a high level of maneuverability and dexterity.

Our research in mobile robotics will focus on unmanned ground vehicles. Specifically we will be working with wheeled mobile robots that travel on flat, two-dimensional terrain. Our robots will be equipped with two wheels using a differential drive steering model. Differential drive mobile robots offer a large range of mobility, due to their wheel setup. Both wheels are controlled independently from the other, and by coordinating the two different speeds, the robot can perform various maneuvers such as: spin in place, move in a straight line, move in a circular path, and follow prescribed trajectories. The mobile robot will also be characterized by nonholonomic kinematic constraints that prevent the wheeled robots from moving sideways, perpendicular to the wheel movement, during its motion. Nonholonomic constraints limit the mobility of mobile robots in their workspace, and since sideway motion is prohibited, robots must move around obstacles in a smooth path with

an appropriate velocity profile. The two-wheel differential drive mobile robots fare better than their four or six wheel counterparts in working with their nonholonomic motion constraints, since the differential drive robot can slow down and even stop and spin on place when difficult motions are required.

2.2 Autonomous Mobile Robot Systems

When designing mobile robot systems, engineers must decide on the level of autonomy for the vehicle, and how it will interact with the human operator. The decision on the level of autonomy depends on the scope of the work and the budget of the project; fully autonomous systems are more complex and expensive solutions, and require more time to develop. In general there are four levels of autonomy for unmanned vehicle systems[17].

The first level is remote control and teleoperation. In this level a human operator controls the robots from a distance, the human performs all the cognitive processes, onboard sensors enable the operator to visualize the location and movement of the platform within its environment, and actuators enable the human to act on the information.

The second level of autonomy is the semi-autonomous mobile robot. In this case, robots are programmed with advanced navigation, obstacle avoidance, and data fusion capabilities that minimize the need for operator interaction.

The third level of autonomy is platform-centric autonomous. Platform-centric autonomous vehicles are fully autonomous unmanned vehicle systems that can undertake complex missions, and can respond to additional commands from a controller without the need for further guidance from an operator.

Finally, the fourth level of autonomy is called network-centric autonomous. Vehicles in this level must be able to receive information from the communications

network and incorporate it in the mission execution, they must respond to appropriate information requests and action commands received from the network. They must also resolve conflicts when commands interfere with each other or interfere with the original mission assigned to the UGV.

2.3 Motion Planning

Some of the most significant challenges confronting autonomous mobile robots lie in the domain of automatic motion planning. The motion planner must find a path for the robot to travel from one configuration to another, while avoiding obstacles. Motion planning algorithms are derived from elements of mechanics, control theory, computational and differential geometry, and computer science. There is generally no single solution to solve motion-planning problems, and controllers are often combinations of various methods from different fields of engineering.

The Piano Movers Problem is a classic path-planning problem. Given a three-dimensional rigid body and a known set of obstacles, the problem is to find a collision-free path for the omnidirectional free-flying piano to move from a start configuration to a goal configuration[9]. The obstacles are assumed to be perfectly known, and execution of the planned path is exact. This method is called offline planning because the planning is finished in advance of the execution. The configuration space is the space of all configurations the robot can achieve. The dimension of the configuration space is equal to the degrees of freedom (DOF) of the system. A piano has six DOF x, y, z, roll, pitch, and yaw. The problem is to find a curve in the configuration space that connects the start and goal points and avoids all configuration space obstacles that arise due to obstacles in the space.

Motion planning consists of four main components: navigation, coverage, localization, and mapping[9]. Firstly, navigation is the problem of finding a collision-free

motion for the robot to travel from one configuration to another. Secondly, coverage is the problem of passing a sensor or tool over all points in the space, determining if all points are available to the robot. Thirdly, localization is the problem of determining the current configuration of the robot in the environment. Finally, mapping is the problem of exploring and sensing an unknown environment to construct a map. Recently it was found that localization and mapping can be combined into a single SLAM (Simultaneous Localization and Mapping) algorithm[53].

An effective motion planner depends heavily on the properties of the robot solving the task. For example, the robot and the environment determine the number of degrees of freedom of the system and the shape of the configuration space. Once we understand the robots configuration space, we can ask if the robot is free to move instantaneously in any direction in its configuration space. Omnidirectional mobile robots can move in any direction in the configuration space, however they are impractical in most robot applications, and are applied more in a simulation context to show the ideal movement of robots. Wheeled mobile robots with nonholonomic constraints are more prevalent in mobile robotics research, and since wheels cannot translate sideways, it is constrained in its movement in the configuration space. Wheeled mobile robots can be modeled using kinematic equations with velocities as controls, or using dynamic equations of motion with force as controls.

The basic strategy in developing motion planner to regulate the motion of mobile robots is: Sense $\rightarrow$ Map $\rightarrow$ Plan $\rightarrow$ Act[4]. Firstly, sensors gain information about the robot pose and the local environment. Secondly, mapping algorithms take in sensor information and develop a two-dimensional map of the terrain to determine the location of obstacles and walls. Thirdly, path-planning algorithms determine the best path, and velocity profile along the path, based on the map, sensor data, and the vehicles nonholonomic constraints. Finally the robot converts velocity data into torque values at the motors of the differential drive mobile robot.

2.3.1 Navigation

Navigation encompasses the ability of the robot to act, based on its knowledge and sensor values, so as to reach its goal position as efficiently and reliably as possible without collision. Two competences are required for mobile robot navigation: path planning and obstacle avoidance[14]. Given a map and a goal location, path planning involves identifying a trajectory that will cause the robot to reach the goal location when executed. Path planning is a strategic problem solving competence, as the robot must decide what to do over the long term to achieve its goals[59]. In comparison, the second competence obstacle avoidance is more of a reactive problem, and requires real-time sensors reading and modulating the trajectory of the robot in order to avoid collisions. Both planning and reacting work together when developing motion planners for mobile robots. Planners and reactors complement each other and are critical to the others success. The navigation challenge for the robot involves executing a course of action to reach its goal position. During the execution the robot must react to unforeseen events in such a way as to still reach the goal.

The goal of path planning is to find a path in the physical space from the initial position to the goal position, while avoiding all collisions with obstacles. Nonholonomic constraints limit the robots mobility[48]. Due to Brocketts theorem[6], it is well known that nonholonomic systems with restricted mobility cannot be stabilized to a desired configuration via differentiable, continuous, pure-state feedback. Different approaches have been proposed, which include discontinuous, hybrid, and time varying control laws. Moreover, researchers sometimes assume omnidirectional motion to simplify the control problem. The control strategies for nonholonomic systems can be divided into two main groups: open-loop strategies and closed-loop feedback strategies. In open-loop strategies the control signal is calculated off-line starting from the knowledge of the initial and final configurations of the system. By

their own nature, these strategies are not able to compensate for disturbances and model errors, therefore in practice the reached configuration may differ significantly from the desired final configuration. In closed-loop strategies the control signal is computed online, based on the knowledge of the actual configuration of the system and the final one. Closed-loop control strategies have a better chance of reaching the goal pose, as long as the nonholonomic constraints allow the motion[20].

2.4 Multi-Robot Systems

There is increasing interest in the development and deployment of groups of mobile robots to perform tasks that may be difficult or impossible for a single robot. Firstly, multiple robots can complete tasks more rapidly and efficiently than single robots. This concept is exploited in applications such as searching for unexploded landmines, where a team of mobile robots can distribute the task of searching the terrain among its members, to increase the overall efficiency of the search. Furthermore, multi-robot systems can perform tasks that are beyond the limits of a single robot. For example a team of unmanned ground vehicles could work together to cooperatively lift or push large objects in the workspace; an operation that is impossible for a single robot. Moreover complex tasks are often less expensive to execute by implementing a group of specialized simpler vehicles, rather than with a single expensive all-purpose platform. As tasks become more complex, having a team of mobile robots, each with their own specialization, is the best method to complete the mission. Finally, when exploring hazardous environments, where failure of one robot should not lead to the failure of the entire mission, a team of mobile robots is the best approach[39]. Multi-robot teams add redundancy, increase the fault tolerance of the group, and are a more robust as a team than single robots.

Multi-robot systems have many benefits over their single robot counterparts,

since they can perform tasks with greater efficiency, less cost, and they present a more robust solution. Teams of mobile robots must coordinate with each other in order to successfully complete tasks. Robots need to allocate jobs, define their workspace, work together, and cooperate with each other to perform their mission. Multi-robot teams exchange information over a wireless network, so all of the robots know where their team members are at all time, what they are working on, and they can direct each other in their tasks[45]. Multi-robot systems are more complex to engineer than single robot systems, and as the number of mobile robots working in an environment increases, the greater the likelihood of inter-robot collisions. A coordination strategy between the robots is instrumental in the successful deployment of multi-robot teams. Collision avoidance strategies alone are not enough, and large groups of mobile robots must have some sense of how to move together as a group[13].

2.5 Formation Control of a Team of Mobile Robots

For large multi-robot systems, navigation strategies for path planning and collision avoidance are insufficient for all of the robots to successfully reach the goal position while avoiding obstacles, and a mechanism of cooperation is required in order for the robots to move effectively and cohesively in the environment. Two popular approaches to group coordination are proposed: self-organizing systems and geometric formations. Firstly, self-organizing systems create a global order out of the local interactions between components of an initially disordered system[41]. Self-organizing systems are spontaneous, they are not directed or controlled by any agent or subsystem, and are regulated by individual behaviors of the agents. The resulting organization is wholly decentralized and distributed over all components of the system. Groups of self-organizing robots look like swarms as they travel

across the environment, where each robot takes a place among the pack and stay a safe distance away from neighboring robots. The swarms also change their shape to accommodate changes in the terrain, to fit into narrow passages and to travel around difficult obstacles. Geometric formations on the other hand take on a more centralized approach to group coordination. They adopt military style formation strategies, where all robots move in a defined manner dictated by the desired shape of the formation, and follow a leader to reach the goal position. Formation shapes must accommodate obstacles in the environment in order for the group to successfully reach the goal position; for example, a group of robots in a V-formation must morph its shape into a platoon formation in order to cross a narrow bridge.

Chapter 3

Literature Review

In this chapter, seven formation controller approaches from literature are examined. Section 3.1 looks at behavior based formations in multi-agent systems. Section 3.2 describes the work contributed to the artificial potential field formation controller. Section 3.3 examines graph theoretic solutions to the multi-robot coordination problem. Section 3.4 looks at formations that move together in a virtual structure. Section 3.5 looks at the leader-follower formation controller and its variations. Section 3.6 describes biologically inspired formations and self-organizing formations. Finally, section 3.7 looks at navigation and formation approaches using fluid mechanics principles.

3.1 Behavior Based Formations

In the behavioral approach, a number of basic behaviors are prescribed, like obstacle avoidance, formation keeping, and goal seeking. The overall control action is a weighted average of the control actions for each basic behavior.

In [1], the author describes how formations can be derived as a result of the culmination of reactive behaviors. In the paper, new formations in multi-robot teams are presented and evaluated based on the behavioral approach. The formation

behaviors are integrated with other navigational behaviors to enable a robotic team to reach navigational goals, avoid hazards and simultaneously remain in formation.

In [12], the paper describes a flexible architecture for modeling thousands of autonomous agents simultaneously. The agents behavior is based on a subsumption architecture in which individual behaviors are prioritized with respect to all others. The primary behavior explored in this work is a group formation behavior based on social potential fields, and this paper extends the social potential field model by introducing a neutral zone within which other behaviors may exhibit themselves. The paper evaluates the effect of social potential fields in the presence of agent death (failure) and imperfect sensory input.

In [25], the authors address the challenge in deploying teams of robots in real-world applications, and develops a system to automate the control of teamwork, such that the designer can focus on the task-work. Existing teamwork architectures seeking to address this challenge are monolithic, in that they commit to interaction protocols at the architectural level, and do not allow the designer to mix and match protocols for a given task. A BITE architecture is presented, a behavior-based teamwork architecture that automates collaboration in physical robots in a distributed fashion. BITE separates task behaviors that control a robot's interaction with its task, from interaction behaviors that control a robot's interaction with its teammates. This distinction provides for flexibility to collaborate effectively. It also allows BITE to synthesize and significantly extend existing teamwork architectures.

In [2], the author addresses a wide range of multi-robot coordinated movement tasks to derive a formation strategy that offers: scalability (the approach should easily scale to any number of agents), locality (the behaviors should depend only on the local sensors of each agent), and flexibility (the behaviors should be flexible so as to support many formation shapes). To provide these features a new behavior-based approach is introduce. The new strategy is based loosely on the way molecules

form crystals. From the point of view of each robot in the group, every other robot has several local attachment sites other robots may be attracted to. This type of attachment site geometry roughly corresponds to molecular covalent bonding. Just as different crystal shapes result from different covalent bond geometries, robot formation shapes are influenced by the attachment site geometries employed.

In [55], a component is constructed through the use of a heterogeneous multi-robot system. The task requires component acquisition, cooperative transport, and cooperative precision manipulation. A behavior-based architecture provides adaptability, and the approach minimizes computation, power, communication, and sensing for applicability to space-related construction efforts.

In [61], the authors examines hybrid systems with behavioral and model-based strategies. They claims that a strict behavior-based approach can scale to higher levels of complexity than many robotics researchers assume, and that the resulting systems are in many cases more efficient and robust than those that rely on classical AI deliberative approaches. The system focuses on cooperative autonomous robots in dynamic environments. Three design principles are introduced for complex cooperative behaviorminimalism, statelessness and tolerance

In [40], the paper describes the use of behaviors as the underlying control. The paper focuses on the role and power of behaviors as a representational substrate in learning policies and models in multi-robot systems, as well as learning from other agents (by demonstration and imitation).

3.2 Artificial Potential Field Formations

In the navigation case, the artificial potential field method creates a field across the robot's map that directs the robot to the goal position. The artificial potential field approach directs a robot as if it were a particle moving in a gradient vector

field. Positively charged particles are attracted to the negatively charged goal, and repulsed by positively charged obstacles. In the multi-robot case, artificial potential fields can be used to bind robots together in a self-organizing formation as the group travels to the goal.

In [3], an artificial potential field swarming method is derived using artificial potential fields generated from normal and sigmoid functions. These functions construct the surface that swarm members travel on, controlling the overall swarm geometry and the individual member spacing. Limiting functions are defined to provide tighter swarm control by modifying and adjusting a set of control variables forcing the swarm to behave according to set constraints, formation shape, and member spacing. The swarm function and limiting functions are combined to control swarm formation, orientation, and swarm movement as a whole. Parameters are chosen based on desired formation as well as user-defined constraints. This approach compared to others, is simple, computationally efficient, scales well to different swarm sizes, to heterogeneous systems, and to both centralized and decentralized swarm models.

In [38], a behavior-based reactive control is developed for the formation control of multiple robots. The combination of potential-based avoidance and following-wall behavior ensures the robots are able to avoid the obstacles smoothly. To get rid of the following-wall behavior when it is not needed, a step of judging its necessity is added. Finally the experiment on the Amigo-Bot robots showed that the robots can return the formation after passing the obstacles.

In [24], a new control algorithm based on a potential function and behavior rules is developed to effectively control the formation of a multiple autonomous underwater vehicle (AUV). Proper potential functions concerning with object, obstacle and the structure of the formation is chosen to design a new distributed control algorithm to make the formation of the multiple AUV system track the target effectively.

In [15] an efficient, simple, and practical real time path planning method for multiple mobile robots in dynamic environments is introduced. Harmonic potential functions are utilized along with the panel method known in fluid mechanics. First, a complement to the traditional panel method is introduced to generate a more effective harmonic potential field for obstacle avoidance in dynamically changing environments. Second, a group of mobile robots working in an environment containing stationary and moving obstacles is considered. Each robot is assigned to move from its current position to a goal position. The group is not forced to maintain a formation during the motion. Every robot considers the other robots of the group as moving obstacles and hence the physical dimensions of the robots are also taken into account. The path of each robot is planned based on the changing position of the other robots and the position of stationary and moving obstacles.

In [30], a control method based on a set of artificial potential functions is described. The type of artificial potential used for the experiments is dependent on the experiment objectives: avoiding collisions between robots and keeping them in the ordered formation, executing task by the formation (e.g. moving formation into desired position), building formation and avoiding collisions with obstacles. In this paper a framework is proposed for the attraction potential function, which allows the system to build formation and repulsion potential function to avoid collisions with obstacles. The main advantage of presented approach is that it is easy scalable because control is based on general rule that determines behavior of all robots.

In [69], collision between robots and the global minimum point, which exist in the traditional artificial potential field TAPF, seriously affect the formation of multi-robot system. The paper constructs a dynamic artificial potential field based on the local information to solve the problem of the TAPF. Collisions between robots are avoided by introducing the repulsion between robots. Adjusting the robot movement direction within the escaping area solves the problem of global minimum point.

In [34], a framework is presented for coordinated and distributed control of multiple autonomous vehicles using artificial potentials and virtual leaders. Artificial potentials define interaction control forces between neighboring vehicles and are designed to enforce a desired inter-vehicle spacing. A virtual leader is a moving reference point that influences vehicles in its neighborhood by means of additional artificial potentials. Virtual leaders can be used to manipulate group geometry and direct the motion of the group. The approach provides a construction for a Lyapunov function to prove closed-loop stability using the system kinetic energy and the artificial potential energy. Dissipative control terms are included to achieve asymptotic stability. The framework allows for a homogeneous group with no ordering of vehicles; this adds robustness of the group to a single vehicle failure.

In [21], a novel approach for representing formation structures in terms of queues and formation vertices, rather than with nodes. Furthermore, the new concept of artificial potential trenches is introduced to effectively control the formation of a group of robots. The scheme improves the scalability and flexibility of robot formations when the team size changes, and at the same time, allows formations to adapt to obstacles. Furthermore, for multi-robot teams to operate successfully in real and unstructured environments, the instant goal method is used to effectively solve the local minima problem.

In [19], a control strategy of multi-agent swarms is derived based on artificial potential functions and the sliding-mode control technique. In that model, the individual interactions are based on artificial potential functions, and the motion of the individuals is along the negative gradient of the combined potential. A general model for vehicle dynamics of each agent (swarm member) is applied using sliding-mode control theory to force their motion to obey the dynamics of the kinematic model. The presented control scheme is robust with respect to disturbances and system uncertainties.

In [42], a framework is proposed for formation stabilization of multiple autonomous vehicles in a distributed fashion. Each vehicle is assumed to have simple dynamics, with a directed (or an undirected) information flow over the formation graph of the vehicles. The goal is to find a distributed control law for each vehicle that makes use of limited information regarding the state of other vehicles. The key idea in formation stabilization is the use of natural potential functions obtained from structural constraints of a desired formation in a way that leads to a collision-free, distributed, and bounded state feedback law for each vehicle.

3.3 Graph Theoretic Formation

Graph theory provides mathematical relations that connect robot agents in a multi-agent network.

In [11] the paper addresses a new approach for modeling and control of multiple teams of mobile robots navigating in a terrain with obstacles, while maintaining a desired formation and changing formations when required. A set of shape variables, r, describe the relative positions of robots, and a control graph, H, describes the behaviors of the robots in the formation. It is assumed that all the robots are equipped with the appropriate sensors to detect and avoid other robots and obstacles in the environment. The framework enables the representation and enumeration of possible control graphs, and the coordination of transitions between any two control graphs. Further, an algorithm is described that allows each team of robots to move between any two formations, while avoiding obstacles. As the number of robots increases, the number of possible control graphs increases. However, because the control computations are decentralized, the algorithms scale with the number of robots.

In [47], the author introduces a class of triangulated graphs for algebraic represen-

tation of formations that specifies a mission cost for a group of vehicles. This representation plus the navigational information allows the system to formally specify and solve tracking problems for groups of vehicles in formations using an optimization-based approach. The approach is illustrated using a collection of six under-actuated vehicles that track a desired trajectory in formation.

In [31] the paper investigates a method for decentralized stabilization of vehicle formations using techniques from algebraic graph theory. The vehicles exchange information according to a pre-specified communication digraph, G. A feedback control is designed using relative information between a vehicle and its neighbors in G. A direct relationship between the rate of convergence to formation and the eigenvalues of the (directed) Laplacian of G are calculated. Various special situations are discussed, including symmetric communication graphs and formations with leaders.

In [16], cooperation among a collection of vehicles, performing a shared task and using inter-vehicle communication to coordinate their actions, is developed. Tools from algebraic graph theory prove useful in modeling the communication network and relating its topology to formation stability. The authors prove a Nyquist criterion that uses the eigenvalues of the graph Laplacian matrix to determine the effect of the communication topology on formation stability. A method is also proposed for decentralized information exchange between vehicles. The information flow can thus be rendered highly robust to changes in the graph, enabling tight formation control despite limitations in inter-vehicle communication capability.

3.4 Virtual Structures

In [67] the formation control problem of multiple mobile robots is investigated. A formation control scheme based on a hierarchical virtual structure is proposed. The mobile robots are divided into clusters according to their distributions in space

and then the motion trajectory of every cluster (virtual structure) is defined, so the motion of virtual structure is transformed to desired trajectory of every robot. Furthermore, a finite-time tracking control algorithm with variable structure is proposed.

In [7], the formation control problem for unicycle mobile robots is studied. A virtual structure control strategy with mutual coupling between the robots is proposed. The rationale behind the introduction of the coupling terms is the fact that these introduce additional robustness with respect to perturbations as compared to typical leader-follower approaches. The applicability of the proposed approach is shown in experiments with a group of mobile robots controlled over a wireless communication network.

In [46], Formation control ideas for multiple spacecraft using the virtual structure approach are presented. If there is no formation feedback from the spacecraft to the virtual structure, the spacecraft will get out of formation when the virtual structure moves too fast for the spacecraft to track. The spacecraft may also get out of formation when the system is affected by internal or external disturbances. To overcome these drawbacks, an idea of introducing formation feedback from the spacecraft to the virtual structure is illustrated in detail. An application of these ideas to multiple spacecraft interferometers in deep space is given.

In [32], an approach to 3D formation tracking control based on virtual structures. In this approach, the virtual structure specifies the formation position of each vehicle, and virtual leaders are constructed ahead of each position for the vehicles to follow. The velocity of the virtual structure is assumed to be piecewise constant to provide zero steady-state error. In order to prevent transients from leading to collisions, deconfliction techniques are applied. Analysis of stability and performance is given, and results are demonstrated in simulation.

In [35], the maintenance of a geometric configuration during cooperative move-

ment is analyzed. To address this problem, the concept of a Virtual Structure is introduced. Using this idea, a general control strategy is developed to force an ensemble of robots to behave as if they were particles embedded in a rigid structure. The method was instantiated and tested using both simulation and experimentation with a set of 3 differential drive mobile robots. Results are presented that demonstrate that this approach is capable of achieving high precision movement that is fault tolerant and exhibits graceful degradation of performance. In addition, this algorithm does not require leader selection as in other cooperative robotic strategies. Finally, the method is inherently highly flexible in the kinds of geometric formations that can be maintained.

3.5 Leader-Following Formations

In [68] a leader-follower pattern is applied to multiple UAVs to maintain a fixed geometrical formation during navigation. In this approach, the leader is commanded to fly on some predefined trajectories, and each follower is controlled to maintain its position in formation using the measurement of its inertial position and the information of the leader position and velocity, obtained through a wireless modem. In order to avoid possible collisions of UAV helicopters in the actual formation flight test, a collision avoidance scheme based on some predefined alert zones and protected zones is employed.

In [51], a framework for controlling groups of autonomous mobile robots is developed to achieve predetermined formations based on leader-following approach. A three-level hybrid control architecture is proposed to implement both centralized and decentralized cooperative control. Under such architecture, the global-level formation control problem of N robots is decomposing into decentralized control problems between N followers and their designated leader. In the leader-follower control level,

two basic controllers are proposed to make the following robot keep relative position with respect to the leader and avoid collisions in the presence of obstacles. Then, graph theory is introduced to formalize specified formation patterns in a simple but effective way, and two types of switching between these formations are also proposed.

In [10], the author formalizes the leader-follower problem in a geometric framework, and a proposed a controller is offered as an alternative to those existing in the literature. It is shown that the geometry of the formation imposes a bound on the maximum admissible curvature of leader trajectory. A peculiar characteristic of the proposed strategy is that the position of the followers is not fixed with respect to the leader reference frame but varies in suitable cones. The formation geometry adapts to the followers dynamics and this allows lower control effort with respect to other approaches based on rigid formations.

In [54], the design of a linear robust dynamic output feedback control scheme for output reference trajectory tracking tasks in a leader-follower non-holonomic car formation. A simplification is proposed on the followers exact open loop position tracking error dynamics, obtained by flatness considerations. Linear Luenberger observers may be readily designed, which include the, self-updating, internal model of the unknown disturbance input vector components as generic time-polynomial models. The proposed Generalized Proportional Integral (GPI) observers, which are the dual counterpart of GPI controllers, achieve a, simultaneous, disturbance estimation and tracking error phase variables estimation. This, on-line, gathered information is used to advantage on the followers linear output feedback controller thus allowing for a simple, yet efficient, disturbance and control input gain cancelation effort. The results are applied to control the fixed time delayed trajectory tracking of the leader path on the part of the follower.

In [58], the paper investigates the stability properties of mobile agent formations which are based on leader following. nonlinear gain estimates are derived that

capture how leader behavior affects the interconnection errors observed in the formation. Leader-to-formation stability (LFS) gains quantify error amplification, relate interconnection topology to stability and performance, and offer safety bounds for different formation topologies. Analysis based on the LFS gains provides insight to error propagation and suggests ways to improve the safety, robustness, and performance characteristics of a formation.

In [36], the paper investigates the leader-following based formation control of nonholonomic mobile robots. A new kinematic model is presented for the leader-follower system using Cartesian coordinates. Based on this new model and the direct Lyapunov method, a globally stable controller is derived for the whole system. Simulation results are included to verify the feasibility of the proposed model and controller.

In [8], a review on the current control issues and strategies on a group of unmanned autonomous vehicles/robots formation is presented. Formation control has broad applications and becomes an active research topic in the recent years. In this paper, a review of key issues in formation control in including the leader-follower method. This paper contributes with a new and interesting consideration on formation control and its application in distributed parameter systems.

3.6 Biologically Inspired and Self-Organizing Formations

Biologically inspired formations mimic successful groupings of animals in nature, such as flocking birds, foraging insects, schooling fish, and swarming bees. Biologically inspired formations often apply self-organizing principles in their motion. Self-organizing systems create organization and structure over time without a centralized controller. It is a process of generating order out of randomness, and can

be though of as reverse entropy. In a self-organization algorithm, the specifications of components are left undefined, and these components are expected to organize themselves until they form a system that possesses the desired functionality.

In [65], the paper deals with formation control strategies based on Virtual Structure (VS) for multi-vehicle systems. Several control laws are proposed for networked multi-nonholonomic vehicle systems in order to achieve VS consensus, VS Flocking and VS Flocking with collision- avoidance. First, Virtual Vehicle for the feedback linearization is considered, and we propose VS consensus and Flocking control laws based on a virtual structure and consensus algorithms. Then, VS Flocking control law considering collision avoidance is proposed and its asymptotical stability is proven.

In [56], the paper revisits the problem of multi-agent flocking. The authors prove that the Olfati-Saber flocking algorithm still enables all the informed agents to move with the desired constant velocity, and an uninformed agent to also move with the same desired velocity if the informed agents can influence it from time to time during the evolution. Numerical simulation demonstrates that a very small group of the informed agents can cause most of the agents to move with the desired velocity and the larger the informed group is the bigger portion of agents will move with the desired velocity. In the situation where the virtual leader travels with a varying velocity, a proposed modification to the Olfati-Saber algorithm shows that the resulting algorithm enables the asymptotic tracking of the virtual leader. That is, the position and velocity of the center of mass of all agents will converge exponentially to those of the virtual leader. The convergent rate is also given.

In [57], the control law is derived that ensures collision avoidance and cohesion of the group exhibiting flocking motion. flocking motion is established, as long as connectivity in the neighboring graph is maintained.

In [33], the problem of multiple robots system formation using a distributed

control method is studied. The paper uses a swarm flocking control algorithm to implement the biods model of Reynolds among multi-robots. With the help of graph theory, a provably-stable flocking control law, which ensures that the internal group formation is stabilized to a desired shape, while all the robots velocities and directions converge to the same. Player/Stage simulation results show that the proposed method can be efficiently applied to multiple robots formation control. With the characteristic of Player/Stage, the algorithm in this paper can be implemented on the real robots with so few or no changes.

3.7 Navigation and Formation Control Based on Fluid Principles

In [64], the paper presents a general framework for coordinated motion control of autonomous swarms in the presence of obstacles. The proposed framework judiciously combines concepts and techniques from potential flows, artificial potentials and dynamic connectivity to realize complex swarm behaviors. To begin with, existing concepts from potential flows in fluid mechanics are used to solve the single-agent navigation problem. As an extension, an analytical solution to the stagnation point problem is provided. The potential flow based framework is then modified significantly to facilitate the coordinated control of swarms navigating through multiple obstacles. Artificial potentials are employed for swarming as well as enhanced obstacle avoidance. A novel concept of dynamic connectivity is utilized to improve the performance of obstacle avoidance (Line of Sight Connectivity) and to organize diverse swarm behaviors (Random Connectivity). Simulation results with a set of developed algorithms are included to illustrate the viability the proposed framework.

In [50], the authors present a novel approach to obstacle avoidance for a group of robots moving in formation. This idea is originally inspired by a phenomenon in

hydrodynamics. In this approach, a virtual robot is introduced as a reference point (beacon) to determine a collision-free trajectory. Taking the virtual point as a basic point, the robot group establishes a rigid body-like formation. Since the collision-freeness of the virtual robot does not guarantee all other robots avoiding obstacles, we employ a flexible formation control scheme in the framework of rigid body-like formation. Two kinds of transformation are introduced to help every robot negotiate obstacles. This approach gives a new principle to deal with obstacle avoidance in formation control for multi-robot system. Simulation results are presented to verify its effectiveness.

In [22], the paper presents a path planning method, based on fluid mechanics, able to deal with unstructured terrain models. The algorithm uses the finite element method to compute a velocity potential function free from local minima. Then, several streamlines are computed as a road map and the optimal path is selected among the candidate paths. The approach is implemented on the Canadian Space Agency (CSA) Mars Robotics Testbed (MRT) rover and tested at the CSA Mars Emulation Terrain (MET). To confirm the feasibility of the method, the path planner has been tested on 284 LIDAR scans collected in a realistic outdoor challenging terrain.

In [27], a computational metaphor for path generation is generated from fluid dynamics. It is powerful because it can find optimal paths an a maze of arbitrary complexity, and it is flexible because it readily adapts to any change in the topology of the maze. With the selection of appropriate boundary conditions, the fluid dynamics metaphor does not suffer from local minima. Finally the topological properties of the path generated by the fluid dynamics metaphor are discussed using tools of topology.

In [37], the paper presents a numerical potential function for point-robot path planning in configuration space based on the theory of fluid mechanics. Ideal fluid

is first simulated using Poissons equation and heuristic path planning algorithms are established by comparisons of the velocity potentials. Several computational techniques are experimented and compared. A bitmap collision detection technique is proposed for non-point robots. This fluid model creates an environment, which is not only free of local minima but also beneficial for navigation control.

In [60], the authors borrow from concepts of hydrodynamic analysis. The paper presents stream functions, which satisfy Laplace's equations as local-minima free methods for producing potential-field based navigation functions in two dimensions. These functions generate smoother paths (i.e. more suited to aircraft-like vehicles) and a method is developed for constructing analytic Stream functions. The effects of introducing multiple obstacles are discussed and current work in this direction is detailed.

Chapter 4

Proposed Navigation and Formation Control Approaches

In this chapter, the proposed navigation and formation controllers will be discussed. Section 4.1 will discuss the proposed navigation controller, modeled after the fluid flow principles of streamlines and the velocity potential. Moreover, section 4.2 and section 4.3 will look at the proposed formation control approaches for a team of homogenous mobile robots. In our research, two formation control approaches will be explained for their overall coordination effectiveness. Section 4.2 will look at the derivation of the reconfiguring Leader-Follower formation controller, that adapts its formation shape in order to navigate the team around and through difficult obstacles. Section 4.3 will expand the velocity potential flow method to a self-organizing formation, that will be able to organize the movement of the team in a decentralized fashion.

4.1 Navigation Using the Velocity Potential Method

For our simulation and experimental work, we needed to develop a navigation controller to bring the team of mobile robots from a start position to a goal position without colliding with obstacles in the environment. For our research work, we decided to look at reactive navigation controllers for the team motion, since they were more adaptable to changes in the environment.

This section will look at the work done to create a reactive navigation controller using the velocity potential method. The velocity potential method is inspired by fluid flow principles, and derives its equations from fluid mechanics. First, section 4.1.1 will look at the strengths and weaknesses of the artificial potential field method, a popular reactive navigation controller used by roboticists. Section 4.1.2 will look at fluid mechanics principles that describe fluid motion. Finally, section 4.1.3 will describe the attractive and repulsive flow equations that regulate the velocity potential navigation controller.

4.1.1 The Artificial Potential Field Method: Strengths and Weaknesses

The artificial potential field method is one of the most popular reactive navigation strategies in mobile robotics. The algorithm was first introduced by [29], and since then many variations on the artificial potential field method have been introduced to improve robot navigation in complex dynamic terrains.

The artificial potential field (APF) method creates a field across the robot's map that directs the robot to the goal position. The APF approach directs a robot as if it were a particle moving in a gradient vector field. Positively charged particles are attracted to the negatively charged goal, and repulsed by positively charged

obstacles. Figure 4.1 [9] illustrates the navigation concept, and shows the attractive and repulsive pull on the robot. The combination of repulsive and attractive forces directs the robot from the start location to the goal location while avoiding obstacles.

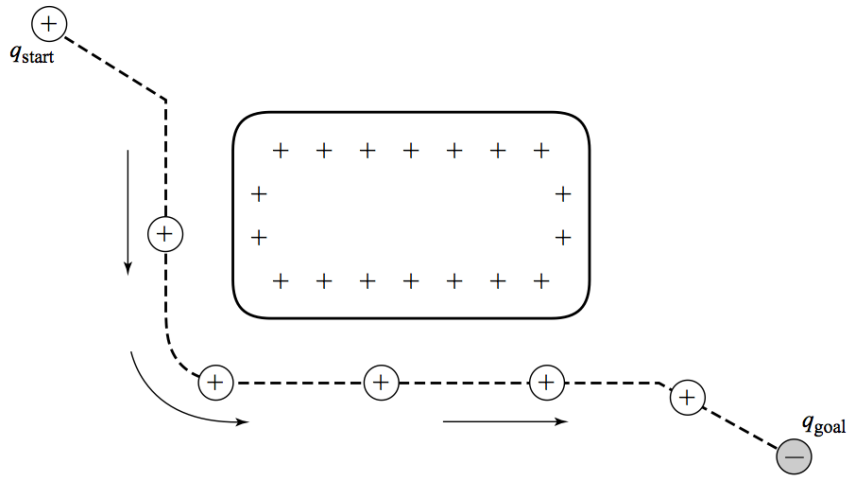

Figure 4.1: The negative charge attracts the robot and the positive charge repels it, resulting in a path, denoted by the dashed line, around the obstacle and to the goal

The robot follows a path "downhill" by following the negative gradient of the potential function U, termed the gradient descent. The robot terminates its motion when it reaches a point where the gradient vanishes $\nabla(q) = 0$. The point where the gradient vanished is termed the critical point, and it is classified as either: a maximum, a minimum, or a saddle point. Figure 4.2 [9]. Figure 4.3a[28] and figure 4.3b[28] illustrate the force field created by the artificial potential field method that directs the robot towards the goal position.

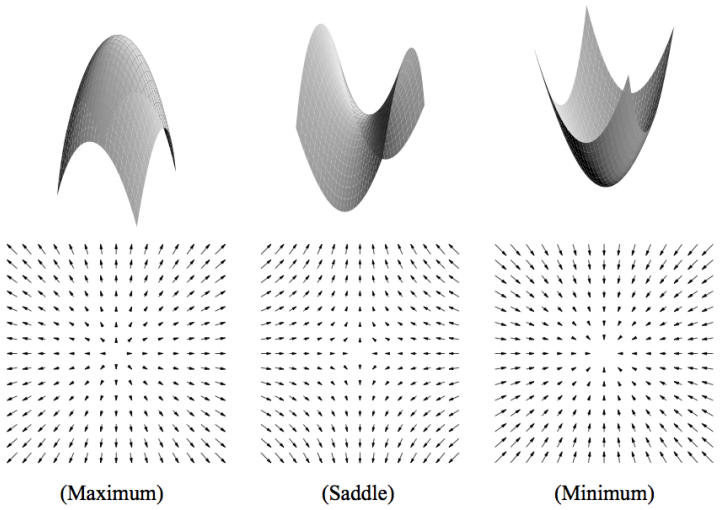

Figure 4.2: Different types of critical points: (top) graphs of functions, (bottom) gradients of functions

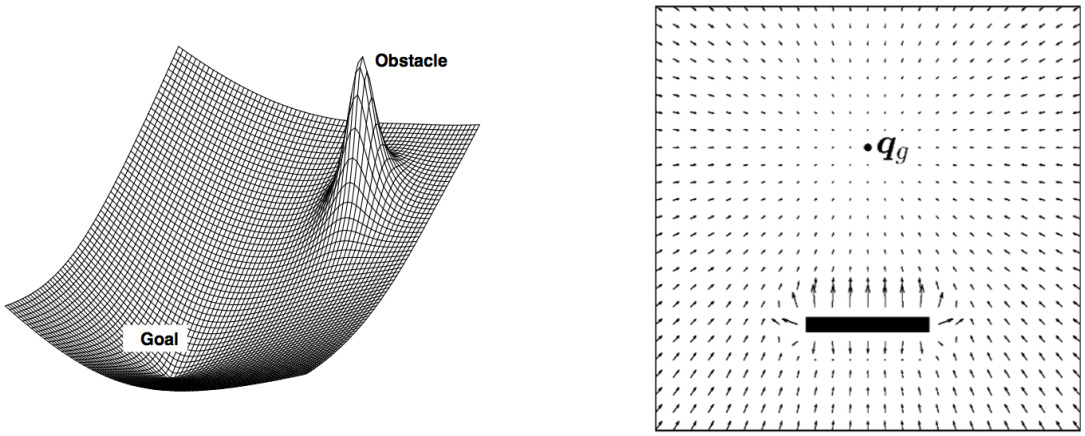

(a) (b)

Figure 4.3: Potential distribution example for an obstacle and a goal

In the artificial potential field method, a net force $F(q)$ is calculated for a robot at coordinates $q = (x, y)$, by determining the gradient of the attractive and repulsive artificial potential field $U(q)$.

$$F(q) = -\nabla U(q) \tag{4.1}$$

$$U(q) = U_{att}(q) + U_{rep}(q) \tag{4.2}$$

The attractive potential field is modeled after a parabolic function. A common attractive field equation is displayed below.

$$U_{att}(q) = \frac{1}{2}\zeta d^2(q, q_{goal}) \tag{4.3}$$

$$\nabla U_{att}(q) = \zeta(q, q_{goal}) \tag{4.4}$$

The repulsive potential keeps the robot away from an obstacle, and its strength is relative to the robot's proximity to the obstacle. As the robot comes closer to the obstacle, the repulsive force acting on the robot increases, to push it far away from a potential collision. The strength of the repulsive force is dependent on the distance $D(q)$, which is the distance to the closest obstacle. In the equation, $Q^* \in \mathbb{R}$ is a factor that allows the robot to ignore obstacles sufficiently far away from it, and ζ and η are attractive and repulsive gains respectively

$$U_{rep}(q) = \begin{cases} \frac{1}{2}\eta\left(\frac{1}{D(q)} - \frac{1}{Q^*}\right)^2, & D(q) \leq Q^* \\ 0, & D(q) > Q^* \end{cases} \tag{4.5}$$

$$\nabla U_{rep}(q) = \begin{cases} \eta\left(\frac{1}{Q^*} - \frac{1}{D(q)}\right)\frac{1}{D^2(q)\nabla D(q)}, & D(q) \leq Q^* \\ 0, & D(q) > Q^* \end{cases} \tag{4.6}$$

4.1.1.1 The Local Minima Problem

The problem that plagues all gradient descent algorithms is the possible existence of local minima in the potential field. There is no guarantee that the gradient descent will find a path the goal position, and the robot may be stranded in the terrain and never reach the goal position. Figure 4.4 [9] shows a diagram of the local minima problem, where the attractive and repulsive forces on the robot have equal and

opposite magnitudes, which stops all robot movement.

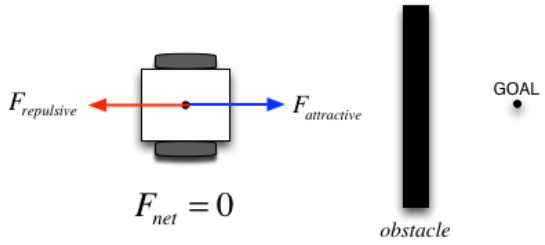

Figure 4.4: The local minima problem

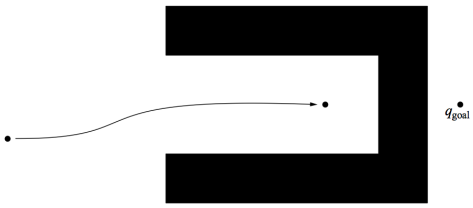
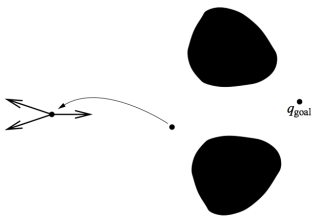
The local minimum problem occurs most often when the robot encounters two types of obstacle geometries: concave and narrow passage. Firstly, figure 4.5a shows a robot entering a concave obstacle. The robot is initially attracted to the goal as it approaches the horseshoe shaped obstacle, and as the robot moves inside the obstacle, the bottom arm of the obstacle deflects the robot upward until the top arm of the horseshoe begins to influence the robot. At this point, the effect of the top and bottom arms keeps the robot halfway between them and the goal continues to attract the robot; the robot reaches a point where the effect of the obstacle's geometry counteracts the attraction of the goal, $\nabla(q) = 0$, and the robot never reaches the goal position. A similar result occurs with the narrow passage, figure 4.5b [9], where the effect of the two adjacent obstacles create a net zero force which stops the robot in place.



(a) Local minimum inside the concave obstacle



(b) Local minimum approaching a narrow passage

Figure 4.5: Local minima cases

4.1.2 Fluid Flow and the Velocity Potential Method

In our research, we were attracted to the simplicity and efficiency of the artificial potential field reactive navigation controller, however we wanted to improve on its results for complex obstacle geometries such as the concave obstacle and narrow passage. We were inspired by fluid flow around obstacles; to create smooth paths that facilitate the nonholonomic constraints of unmanned ground vehicles. Figure 4.6[18] shows the streamlines of fluid flowing over an automobile in a wind tunnel.

Figure 4.6: Streamlines over an automobile in a wind tunnel

The objective was to design a navigation controller that would lead the robots on streamlines, flowing around obstacles and towards a goal position. For incompressible flow, the velocity vector of the fluid always points tangent to the streamline. Figure 4.7[44] shows the motion of fluid streamlines over an airfoil shape. When the velocity is zero there is no unique direction for the streamline, and the streamline can branch out into different directions. This point is called the stagnation point.

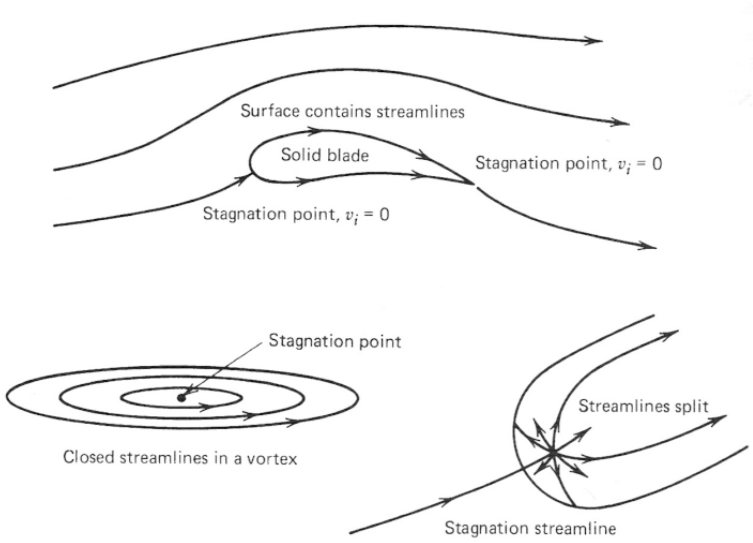


Figure 4.7: Streamline patterns with stagnation points

Streamlines are everywhere tangent to the velocity vectors, and their equations in the two-dimensional plane are represented by the stream function $\psi = \psi(x, y)$ [49]. The stream function is very useful in describing fluid flows, and all properties of the flow including velocities and pressure could be related to it; the streamline is a single scalar unknown that can yield a complete description of the flow. By knowing the stream function of the fluid, velocity parameters u and v, velocity in the x and y directions respectively, can be calculated according to the equation below.

$$u = \frac{\delta\psi}{\delta y} \tag{4.7}$$

$$v = -\frac{\delta\psi}{\delta x} \tag{4.8}$$

Moreover, the fluid velocity can be calculated in cylindrical coordinates based on the stream function ψ.

$$V_r = -\frac{1}{r}\frac{\delta\psi}{\delta\theta} \tag{4.9}$$

$$V_\theta = -\frac{\delta\psi}{\delta r} \tag{4.10}$$

The velocity potential function ϕ is a companion function to the stream function ψ, to describe the flow of fluid. The velocity potential function is also a single scalar variable $\phi = \phi(x, y, t)$ that can be used to calculate flow velocities for irrotational flow according to the equation below[52].

$$u = -\frac{\delta\phi}{\delta x} \tag{4.11}$$

$$v = -\frac{\delta\phi}{\delta y} \tag{4.12}$$

The cylindrical velocity values can be calculated from the equations:

$$V_r = \frac{1}{r}\frac{\delta\phi}{\delta r} \tag{4.13}$$

$$V_\theta = -\frac{1}{r}\frac{\delta\phi}{\delta\theta} \tag{4.14}$$

Since, in an irrotational flow, the velocity field may be defined by the potential function ϕ, the theory is often referred to as the potential flow theory[66].

4.1.2.1 Elementary Plane Flows

Many methods exist for determining the stream function *psi* and the velocity potential function *phi* for a fluid motion[23]. A popular method utilizes the stream function and velocity potential function for five elementary plane flows, and develops the ψ and ϕ functions by combining the elementary flow models. In this section,

the five elementary plane flows are explained and their stream function and velocity potential function are listed.

Firstly, the uniform flow model in figure 4.8[18] is used for determining ψ and ϕ for fluid flowing in a straight path in the positive x-direction at a constant linear velocity.

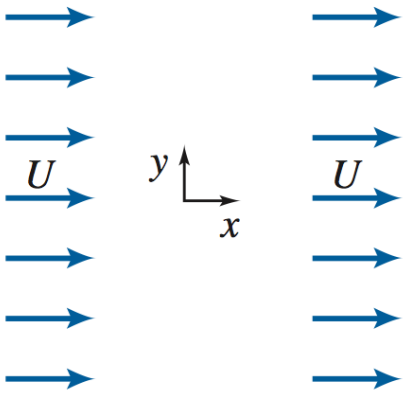

Figure 4.8: Uniform flow

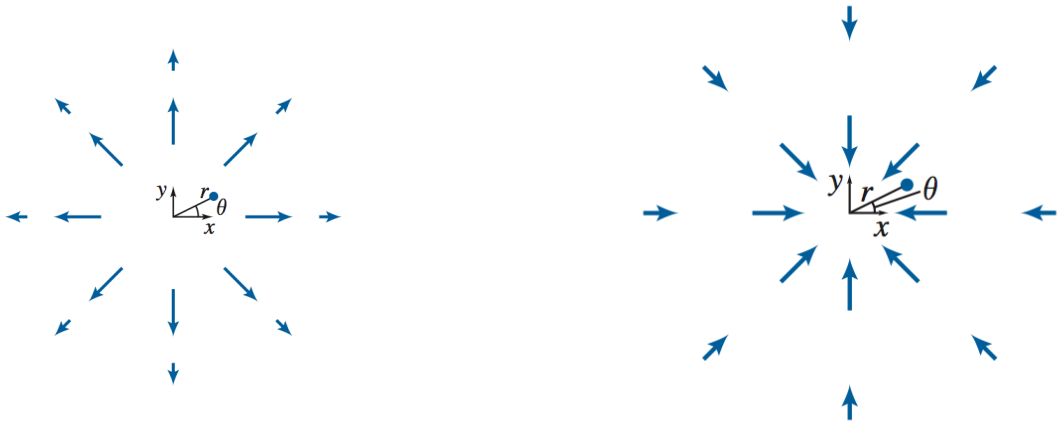
$$\psi = Uy \tag{4.15}$$

$$\phi = -Ux \tag{4.16}$$

Furthermore, the source and sink flows, figure 4.9a[18] and figure 4.9b[18], shows the flow of fluid travelling away from the orgin and the flow of fluid moving toward the origin respectively. Their stream function and velocity potential functions are listed below.



(a) Source flow

(b) Sink flow

Figure 4.9: Source and Sink Flow

Source flow (from origin):

$$\psi = \frac{q}{2\pi}\theta \tag{4.17}$$

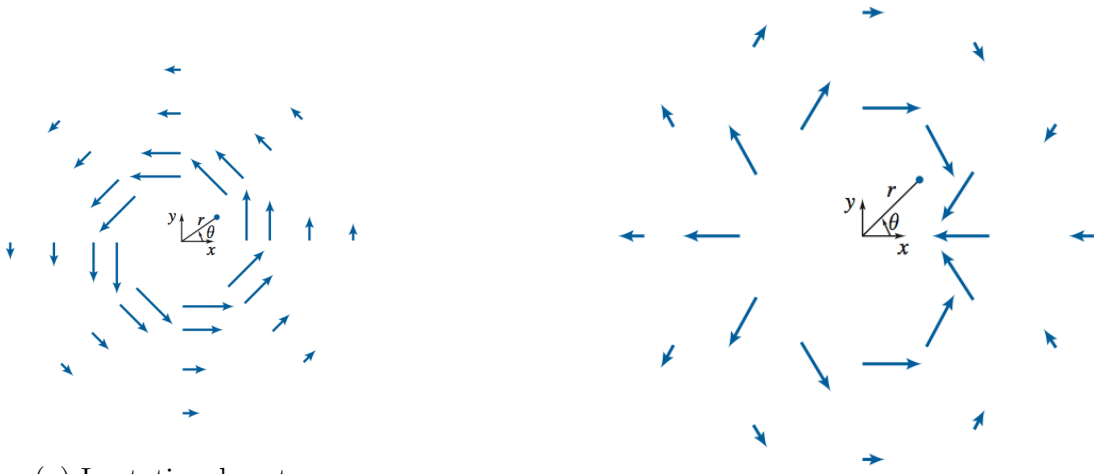
$$\phi = -\frac{q}{2\pi}\ln r \tag{4.18}$$

Sink flow (toward origin):

$$\psi = -\frac{q}{2\pi}\theta \tag{4.19}$$

$$\phi = \frac{q}{2\pi}\ln r \tag{4.20}$$

Moreover, figure 4.10a[18] and figure 4.10b[18] show the fluid flow of an irrotational vortex and doublet. Their equations for ψ and ϕ are calculated as follows:



(a) Irrotational vortex

(b) Doublet

Figure 4.10: Irrotational and Vortex Flow

Irrotational vortex (counterclockwise, center at origin):

$$\psi = -\frac{K}{2\pi}\ln r \tag{4.21}$$

$$\phi = -\frac{K}{2\pi}\theta \tag{4.22}$$

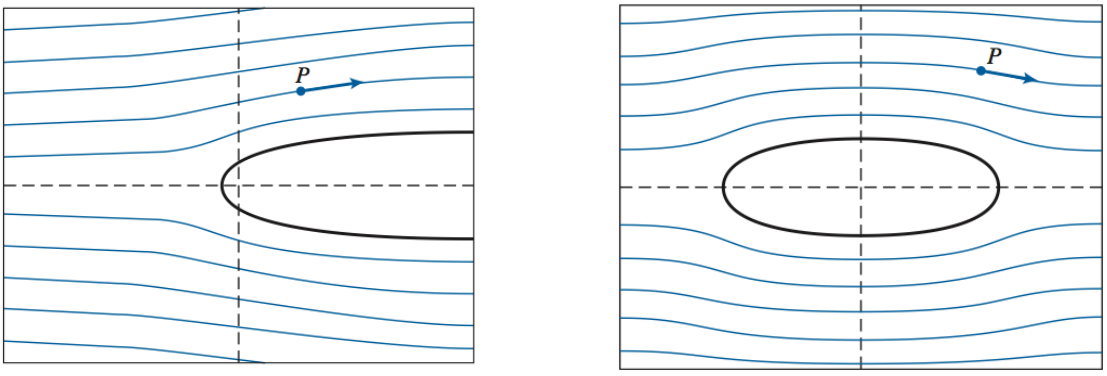
Doublet (center at origin):

$$\psi = -\frac{\Lambda \sin\theta}{r} \tag{4.23}$$

$$\phi = -\frac{\Lambda \cos\theta}{r} \tag{4.24}$$

4.1.2.2 Superposition of Elementary Plane Flows

Using the elementary plane flow model, complex flows can be approximated by combining various elementary flows. Figure 4.11a[18] and figure 4.11b[18] show the flow around an obstacle when combining the (1) source and uniform flow, and (2) source, sink, and uniform flow, respectively.



(a) Source and uniform flow

(b) Source, sink, and uniform flow

Figure 4.11: Superposition Flow 1

Source and uniform flow (flow past a half-body)

$$\psi = \frac{q}{2\pi}\theta + Ur\sin\theta \tag{4.25}$$

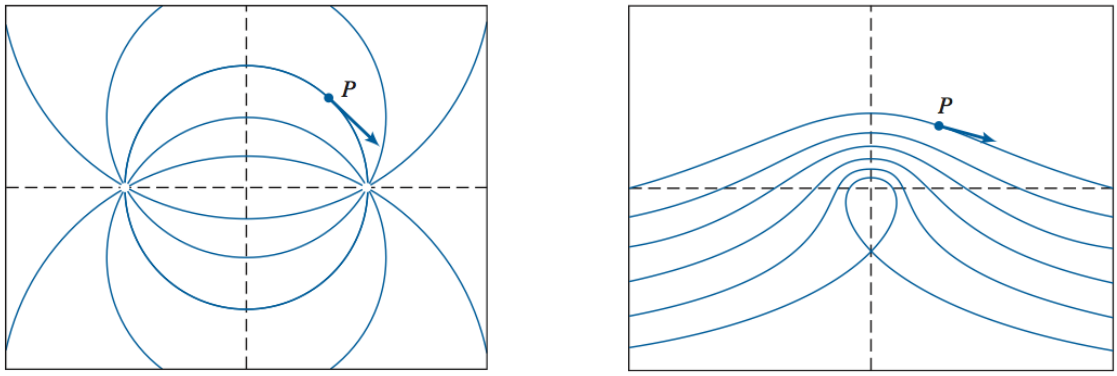
$$\phi = -\frac{q}{2\pi}\ln r - Ur\cos\theta \tag{4.26}$$

Source, sink, and uniform flow (flow past a Rankine body)

$$\psi = \frac{q}{2\pi}(\theta_1 - \theta_2) + Ur\sin\theta \tag{4.27}$$

$$\phi = \frac{q}{2\pi}\ln r\frac{r_2}{r_1} - Ur\cos\theta \tag{4.28}$$

Moreover, figure 4.12a[18] and figure 4.12b[18] show the flow of fluid when combining the (1) source and sink, and (2) vortex and uniform flow, elements respectively.



(a) Source and sink (b) Vortex and uniform flow

Figure 4.12: Superposition Flow 2

Source and sink (equal strength, separation distance on x-axis = 2a)

$$\psi = \frac{q}{2\pi}(\theta_1 - \theta_2) \tag{4.29}$$

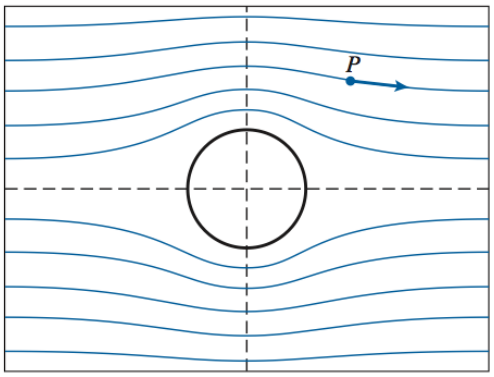
$$\phi = \frac{q}{2\pi} \ln r\frac{r_2}{r_1} \tag{4.30}$$

Vortex (clockwise) and uniform flow

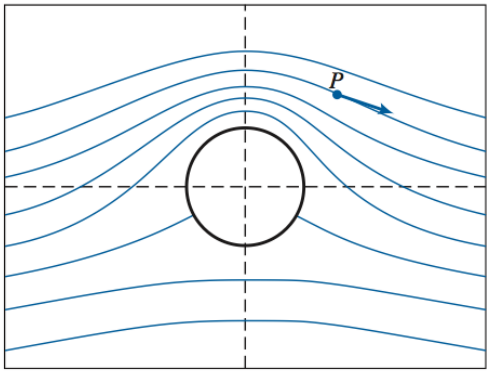
$$\psi = \frac{K}{2\pi} \ln r + ur \sin\theta \tag{4.31}$$

$$\phi = \frac{K}{2\pi}\theta - Ur\cos\theta \tag{4.32}$$

Furthermore, figure 4.13a[18] and figure 4.13b[18] show the flow characteristics when combining (1) the doublet and uniform flow, and (2) the doublet, vortex, and uniform flow, respectively.



(a) Doublet and uniform flow



(b) Doublet, vortex, and uniform flow

Figure 4.13: Superposition Flow 3

Doublet and uniform flow (flow past a cylinder)

$$\psi = U\left(r - \frac{\Lambda}{Ur}\right)\sin\theta \tag{4.33}$$

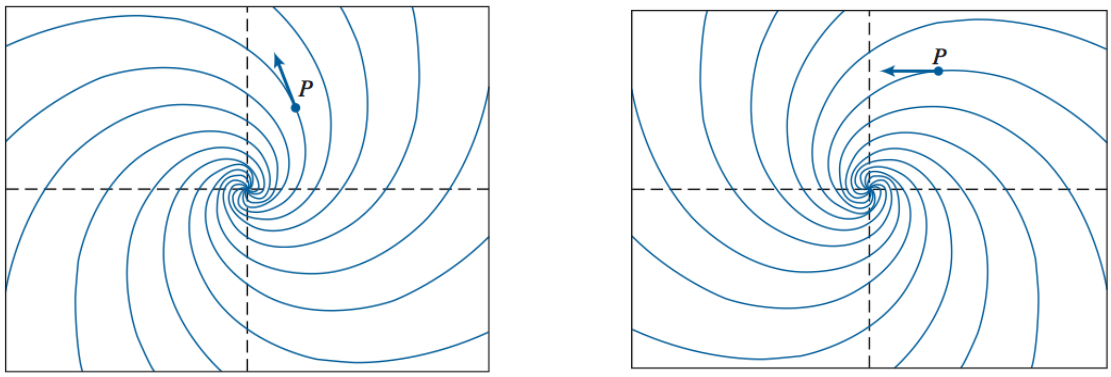
$$\phi = -\frac{\Lambda\cos\theta}{r} - Ur\cos\theta \tag{4.34}$$

Doublet, vortex (clockwise), and uniform flow (flow past a cylinder with circulation)

$$\psi = -\frac{\Lambda\sin\theta}{r} + \frac{K}{2\pi}\ln r + Ur\sin\theta \tag{4.35}$$

$$\phi = -\frac{\Lambda\cos\theta}{r} + \frac{K}{2\pi}\theta - Ur\cos\theta \tag{4.36}$$

In addition, figure 4.14a[18] and figure 4.14b[18] show the flow characteristics and equations when combining (1) a source and vortex, and (2) a sink and vortex, respectively.



(a) Source and vortex

(b) Sink and vortex

Figure 4.14: Superposition Flow 4

Source and vortex (spiral vortex)

$$\psi = \frac{q}{2\pi}\theta - \frac{K}{2\pi}\ln r \tag{4.37}$$

$$\phi = -\frac{q}{2\pi}\ln r - \frac{K}{2\pi}\theta \tag{4.38}$$

Sink and vortex

$$\psi = -\frac{q}{2\pi}\theta - \frac{K}{2\pi}\ln r \tag{4.39}$$

$$\phi = \frac{q}{2\pi}\ln r - \frac{K}{2\pi}\theta \tag{4.40}$$

Finally, figure 4.15 shows the vortex pair that is created when combining two vortices of equal strength and opposite rotation at a given separation distace on the x-axis.

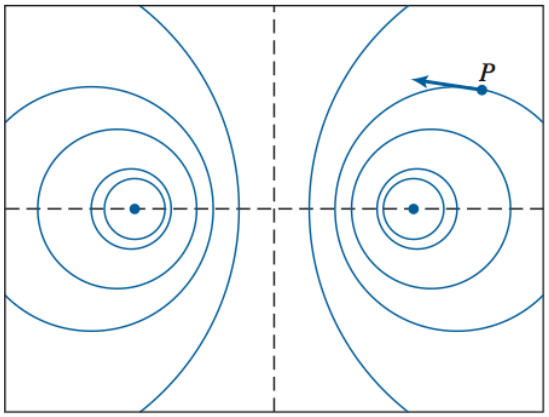


Figure 4.15: Vortex pair

Vortex pair (equal strength, opposite rotation, separation distance on x-axis = 2a)

$$\psi = \frac{K}{2\pi} \ln \frac{r_2}{r_1} \tag{4.41}$$

$$\phi = \frac{K}{2\pi}(\theta_2 - \theta_1) \tag{4.42}$$

4.1.3 Proposed Navigation Controller using the Velocity Potential Flow Theory

For our reactive navigation controller, we implemented the velocity potential flow functions for two desired movements. Firstly, we incorporated the uniform flow equation to describe the flow of the vehicle towards the goal position. The attractive flow is set to travel at the maximum linear velocity set by the user. Figure 4.16 shows a differential drive mobile robot moving with the attractive flow towards the goal position.

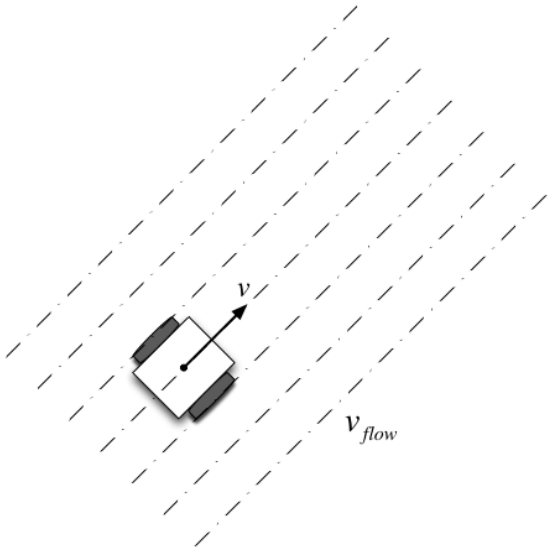

Figure 4.16: Attractive velocity flow

Secondly, we used the spiral vortex (source and vortex) potential flow function to push the robot away and around the obstacles. Figure 4.17 shows the path of the robot as it approaches the obstacle, and changes course to avoid collision, along the flowlines of the spiral vortex.

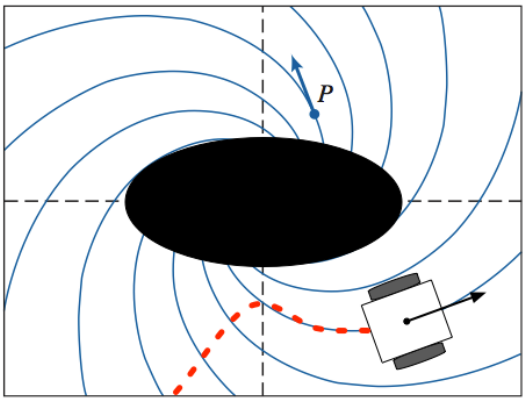

Figure 4.17: Repulsive spiral vortex

The normal and tangential velocities of the robot as it travels along the sprial vortex can be calculated from the cylindrical velocity equations. The velocity potential function for the spiral vortex was found to be:

$$\phi = -\frac{q}{2\pi}\ln r - \frac{K}{2\pi}\theta \tag{4.43}$$

By applying the cylindrical velocity equations from section 4.1.2, the normal and tangential velocities were calculated to be:

$$V_r = \frac{1}{r}\frac{\delta\phi}{\delta r} \tag{4.44}$$

$$V_r = -\frac{q}{2\pi}\left(\frac{1}{r}\right) \tag{4.45}$$

$$V_r = -\frac{A}{r} \tag{4.46}$$

$$V_\theta = -\frac{1}{r}\frac{\delta\phi}{\delta\theta} \tag{4.47}$$

$$V_\theta = \frac{1}{r}\left(-\frac{K}{2\pi}\right) \tag{4.48}$$

$$V_\theta = -\frac{B}{r} \tag{4.49}$$

Where A and B are constants.

4.1.4 Initial Parameters

When designing the algorithm for the reactive navigation controller with the velocity potential method, it was decided that the vehicle would flow towards the goal using a uniform flow field. The vehicle would travel on a straight line path from the initial (x, y) coordinate to the goal (x, y) coordinate. If the vehicle was not initially pointing at goal, it would continue to travel at the same linear velocity, but would also rotate slowly until it pointed in the direction of the goal. When the vehicle entered the region of interest around the goal (dashed circle), it was designed to

automatically slow down and then stop at the goal position. FIgure 4.18 shows the mobile robot velocity and angle parameters, the distance to the goal ρ_G, and the region of interest around the goal position. The robot parameters are listed below:

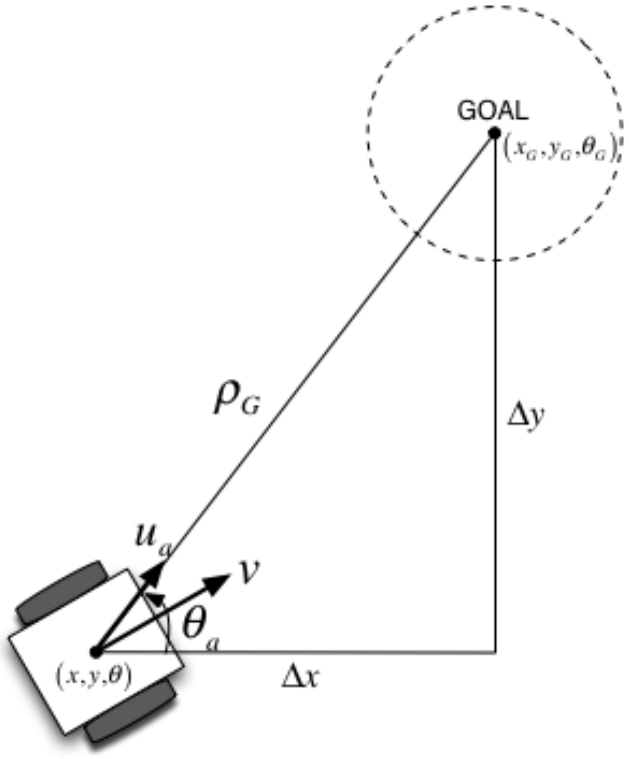

Figure 4.18: Attractive velocity variables

Vehicle current position

$$(x, y, \theta) \tag{4.50}$$

Goal position

$$(x_G, y_G, \theta_G) \tag{4.51}$$

Maximum linear and angular velocity (chosen by the user)

$$v_{max}, \omega_{max} \tag{4.52}$$

The first step in the procedure is to calculate the distance and angle variables.

Distance from the current position to the goal position

$$\rho_G = \sqrt{(x_G - x)^2 + (y_G - y)^2} \tag{4.53}$$

Desired vehicle angle to goal

$$\theta_a = \tan^{-1}\left[\frac{(y_G - y)}{(x_G - x)}\right] \tag{4.54}$$

Let $\Delta\theta$ be the difference between the desired angle and the current vehicle angle

$$\Delta\theta_a = \theta_a - \theta \tag{4.55}$$

4.1.4.1 Calculating the attractive velocity

The goal radius, the critical radius around the goal position ρ_{GR}, is a distance set by the user. It is used in the relation $f(\rho_G, \rho_{GR})$ to slow down and eventually stop the vehicle at the goal position when it enters the goal radius.

$$f(\rho_G, \rho_{GR}) = e^{-\rho_G/\rho_{GR}} \tag{4.56}$$

We initally set the magnitude of the attractive velocity to be equal to the maximum speed of the robot.

$$|u_a| = v_{max} \tag{4.57}$$

The attractive component of velocity is then calculated as follows:

$$u_a = |u_a|(\cos\theta_a + j\sin\theta_a) \tag{4.58}$$

If there are no obstacles in view, the final velocity command is listed below.

$$v_a = k_a(1 - f(\rho_G, \rho_{GR}))u_a \tag{4.59}$$

The angular velocity is then found, at a check is made to make sure the the attractive angular velocity lies within the safe driving bounds for the robot unit.

$$\omega_a = k_a(1 - f(\rho_G, \rho_{GR}))\frac{\Delta\theta_a}{\Delta t} \tag{4.60}$$

4.1.4.2 Calculating repulsive velocity

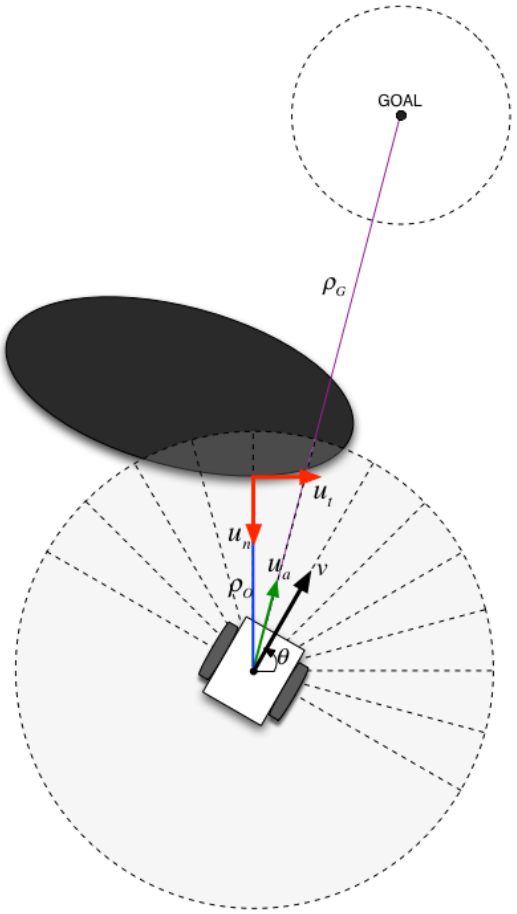

Figure 4.19: Attractive and repulsive velocity variables

The magnitude of the normal and tangent velocity vectors is determined from

equation 4.46 and equation 4.49.

$$|u_n| = |u_t| = \frac{1}{\rho_O} \tag{4.61}$$

As the robot comes closer to the obstacle, the following relation would slow the vehicle down, so that it would have time to react and navigate around the obstacle.

$$f(\rho_O, \rho_{OR}) = e^{-\rho_O/\rho_{OR}} \tag{4.62}$$

Normal vector angle

$$\theta_n = \theta_O - \pi \tag{4.63}$$

Tangent vector angle

$$\theta_t = \theta_n \pm \frac{\pi}{2} \tag{4.64}$$

The normal velocity command

$$u_n = |u_n|(\cos\theta_n + j\sin\theta_n) \tag{4.65}$$

The tangent velocity command

$$u_t = |u_t|(\cos\theta_t + j\sin\theta_t) \tag{4.66}$$

The resultant vector R is found by summing the normal vector with the tangent vector. The resultant vector has x-component R_x, and y-component R_y. The angle of the resultant vector is the new desired angle of the robot

$$\theta_{new} = \tan^{-1}\left(\frac{R_y}{R_x}\right) \tag{4.67}$$

The change in the obstacle angle is calculated

$$\Delta\theta_O = \theta_{new} - \theta \tag{4.68}$$

Velocity command around the obstacle

$$v_O = k_n u_n f(\rho_O, \rho_{OR}) + k_t u_t f(\rho_O, \rho_{OR}) \tag{4.69}$$

Final velocity command including the attractive and repulsive velocities.

$$v_R = k_a u_a (1 - f(\rho_G, \rho_{GR})) + v_O = k_n u_n f(\rho_O, \rho_{OR}) + k_t u_t f(\rho_O, \rho_{OR}) \tag{4.70}$$

$$\omega_R = k_o f(\rho_G, \rho_{GR}) \frac{\Delta\theta_O}{\Delta t} \tag{4.71}$$

4.1.5 Robot Navigation Around Complex Obstacles using the Velocity Potential Method

In our experiments, we will be testing the velocity potential flow algorithm on complex obstacle geometries such as the concave obstacle and the narrow passage obstacle. Figure 4.20 and figure 4.21 show the concave obstacle and narrow passage geometries, and diplay how the robot will tackle these two obstacles in the velocity potential approach.

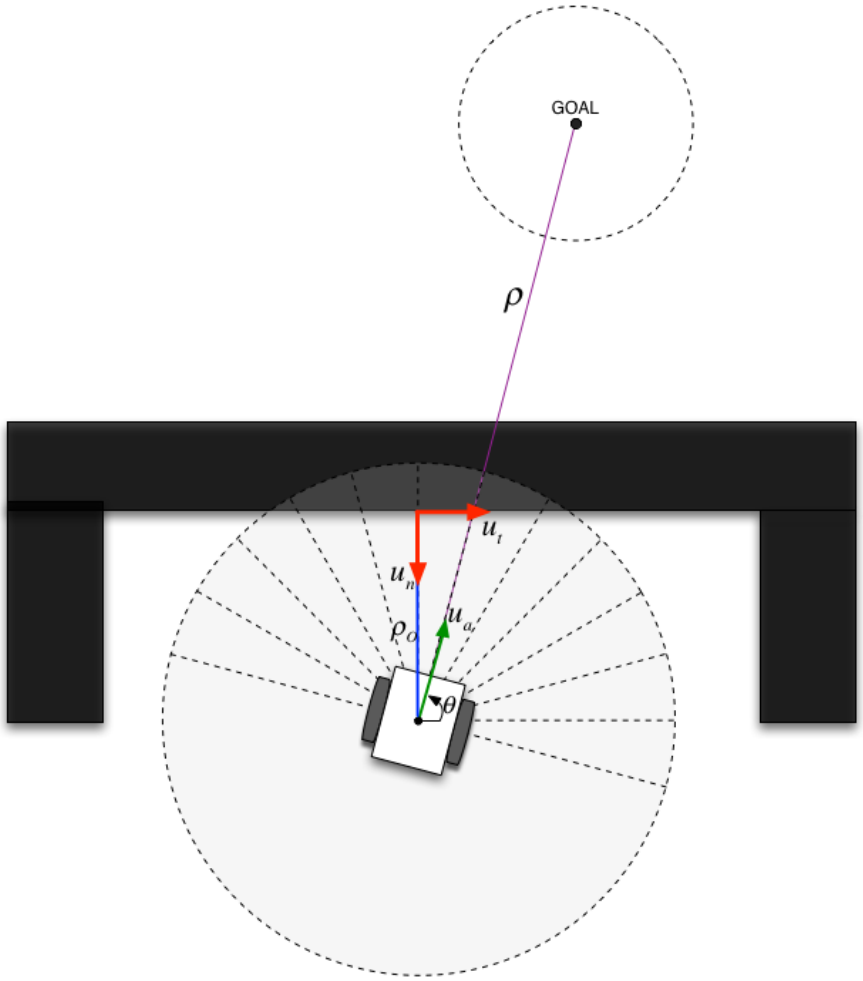

Figure 4.20: Robot approaching a concave obstacle

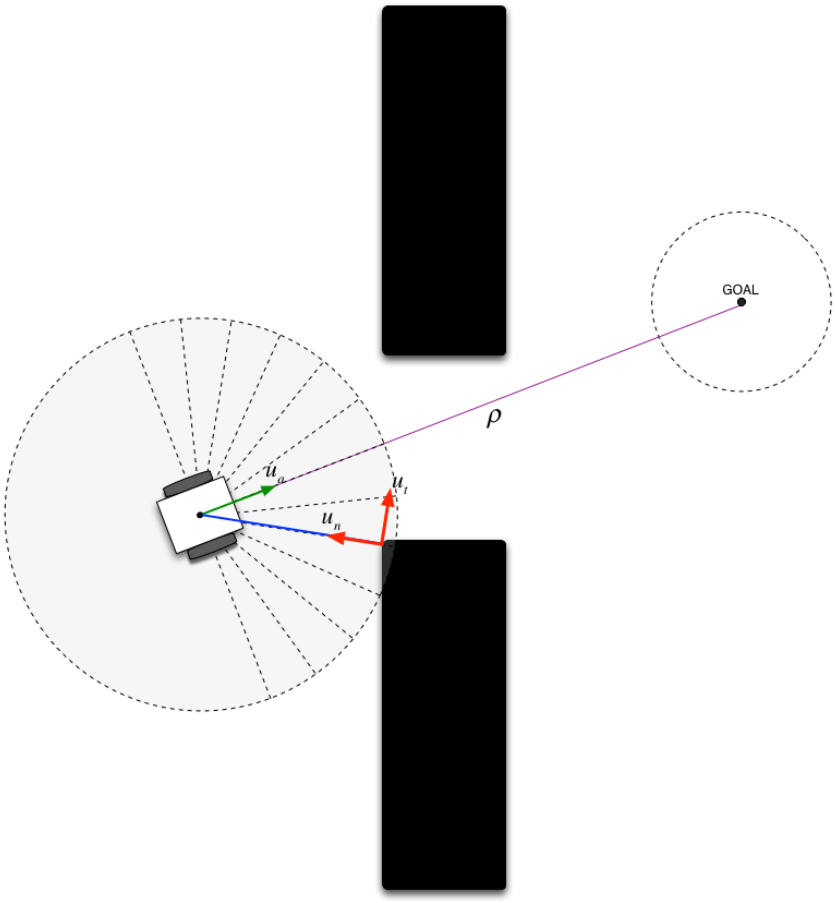

Figure 4.21: Robot approaching a narrow passage

4.2 Reconfiguring Geometric Formations using the Leader Follower Method

In Chapter 3: Literature Review, several formation control methodologies were examined, including: self-organizing systems, swarm systems, formations modeled after biological systems, virtual structures, and leader-following formations. In our analysis, we were attracted to the Leader-Follower formation control method. The leader-follower methodology, is a geometric formation controller that create formations in specific group shapes that are defined by the user.

The leader-follower formation will use geometry principles between the leader and follower robot, to get a follower vehicle to continuously track the leader. Figure 4.22 shows the initial pose of the leader and follower robots, and their variables ρ, α, and ψ, that describes the position and orientation of the follower with respect to the leader.

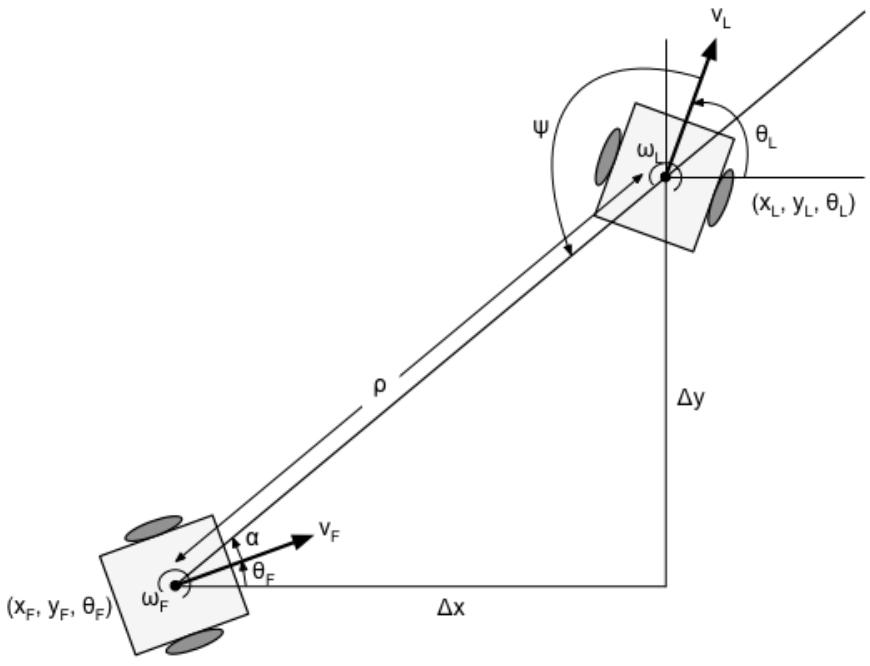

Figure 4.22: Leader-Follower geometry

Most of the calculations for the leader-follower formation are carried out in polar coordinates. The first step in the methodology is to convert Cartesian (x, y, θ) coordinates to polar (ρ, α, ψ) coordinates.

$$\rho = \sqrt{(x_L - x_F)^2 + (y_L - y_F)^2} \tag{4.72}$$

$$\alpha = \tan^{-1} \frac{(y_L - y_F)}{(x_L - x_F)} - \theta_F \tag{4.73}$$

$$\psi = \alpha + \theta_F - \theta_L + \pi \tag{4.74}$$

We then find the derivative of the distance variable $\dot{\rho}$

$$\rho^2 = (x_L - x_F)^2 + (y_L - y_F)^2 \tag{4.75}$$

$$2\rho\dot{\rho} = 2(x_L - x_F)(\dot{x_L} - \dot{x_F}) + 2(y_L - y_F)(\dot{y_L} - \dot{y_F}) \tag{4.76}$$

Let,

$$(x_L - x_F) = \rho\cos(\alpha + \theta_F) \tag{4.77}$$

$$(y_L - y_F) = \rho\sin(\alpha + \theta_F) \tag{4.78}$$

Sub into equation 4.76

$$\rho\dot{\rho} = (\dot{x_L} - \dot{x_F})\rho\cos(\alpha + \theta_F) + (\dot{y_L} - \dot{y_F})\rho\sin(\alpha + \theta_F) \tag{4.79}$$

$$\dot{\rho} = (\dot{x_L} - \dot{x_F})\cos(\alpha + \theta_F) + (\dot{y_L} - \dot{y_F})\sin(\alpha + \theta_F) \tag{4.80}$$

Let,

$$(\dot{x_L} - \dot{x_F}) = v_L \cos\theta_L - v_F \cos\theta_F \tag{4.81}$$

$$(\dot{y_L} - \dot{y_F}) = v_L \sin\theta_L - v_F \sin\theta_F \tag{4.82}$$

Sub into equation 4.80

$$\begin{aligned}\dot{\rho} = v_L \cos\theta_L \cos(\alpha + \theta_F) - v_F \cos\theta_F \cos(\alpha + \theta_F) \\ + v_L \sin\theta_L \sin(\alpha + \theta_F - v_F \sin\theta_F + v_L \sin\theta_L \sin(\alpha + \theta_F)\end{aligned} \tag{4.83}$$

Expand and simplify

$$\dot{\rho} = v_L \cos(\theta_L - \alpha - \theta_F) - v_F \cos(\theta_F - \alpha - \theta_F) \tag{4.84}$$

$$\dot{\rho} = v_L \cos(\theta_L - \alpha - \theta_F) - v_F \cos(-\alpha) \tag{4.85}$$

According to the geometry,

$$\theta_L - \alpha - \theta_F = \pi - \psi \tag{4.86}$$

So,

$$\dot{\rho} = -v_L \cos\psi - v_F \cos\alpha \tag{4.87}$$

Find $\dot{\alpha}$

$$\tan(\alpha + \theta_F) = \frac{y_L - y_F}{x_L - x_F} \tag{4.88}$$

$$\sin(\alpha + \theta_F)(x_L - x_F) = \cos(\alpha + \theta_F)(y_L - y_F) \tag{4.89}$$

Take the derivative

$$\begin{aligned}(\dot{\alpha} + \dot{\theta_F})\cos(\alpha + \theta_F)(x_L - x_F) + (\dot{x_L} - \dot{x_F})\sin(\alpha + \theta_F) \\ = -(\dot{\alpha} + \dot{\theta_F})\sin(\alpha + \theta_F)(y_L - y_F) + (\dot{y_L} - \dot{y_F})cos(\alpha + \theta_F)\end{aligned} \tag{4.90}$$

Let,

$$(\dot{x_L} - \dot{x_F}) = v_L \cos\theta_L - v_F \cos\theta_F \tag{4.91}$$

$$(\dot{y_L} - \dot{y_F}) = v_L \sin\theta_L - v_F \sin\theta_F \tag{4.92}$$

$$(x_L - x_F) = \rho\cos(\alpha + \theta_F) \tag{4.93}$$

$$(y_L - y_F) = \rho\sin(\alpha + \theta_F) \tag{4.94}$$

Expand and simplify

$$\rho(\dot{\alpha} + \dot{\theta_F}) = v_L \sin(\theta_L - \alpha - \theta_F) - v_F \sin(-\alpha) \tag{4.95}$$

According to the geometry

$$\theta_L - \alpha - \theta_F = \pi - \psi \tag{4.96}$$

Sub in

$$\rho(\dot{\alpha} + \dot{\theta_F}) = v_L \sin\psi + v_F \sin\alpha \tag{4.97}$$

Then,

$$\dot{\alpha} = \frac{v_F \sin\alpha}{\rho} + \frac{v_L sin\psi}{\rho} - \dot{\theta_F} \tag{4.98}$$

Find $\dot{\psi}$

$$\psi = \alpha + \theta_F - \theta_L + \pi \tag{4.99}$$

Take the derivative

$$\dot{\psi} = \dot{\alpha} + \dot{\theta_F} - \dot{\theta_L} \tag{4.100}$$

$$\dot{\psi} = \frac{v_F \sin\alpha}{\rho} + \frac{v_L sin\psi}{\rho} - \dot{\theta_L} \tag{4.101}$$

In matrix form

Set

$$\omega_L = \dot{\theta_L} \tag{4.102}$$

$$\omega_F = \dot{\theta_F} \tag{4.103}$$

$$\begin{bmatrix} \dot{\rho} \\ \dot{\alpha} \\ \dot{\psi} \end{bmatrix} = \begin{bmatrix} -\cos\alpha & 0 \\ \frac{sin\alpha}{\rho} & -1 \\ \frac{sin\alpha}{\rho} & 0 \end{bmatrix} \begin{bmatrix} v_F \\ \omega_F \end{bmatrix} + \begin{bmatrix} -\cos\psi & 0 \\ \frac{sin\psi}{\rho} & 0 \\ \frac{sin\psi}{\rho} & -1 \end{bmatrix} \begin{bmatrix} v_L \\ \omega_L \end{bmatrix} \tag{4.104}$$

4.2.1 Controller

Let ρ_d be the desired distance between the two vehicles, and let α_d be the desired angle between the follower's direction of motion an ρ

$$\dot{\rho} = -k(\rho - \rho_d) \tag{4.105}$$

$$\dot{\alpha} = -k(\alpha - \alpha_d) \tag{4.106}$$

Where $k > 0$

In matrix form

$$\begin{bmatrix} \dot{\rho} \\ \dot{\alpha} \end{bmatrix} = \begin{bmatrix} k & 0 \\ 0 & k \end{bmatrix} \begin{bmatrix} \rho - \rho_d \\ \alpha - \alpha_d \end{bmatrix} \tag{4.107}$$

Find the follower's velocity and angular velocity

$$\begin{bmatrix} \dot{\rho} \\ \dot{\alpha} \end{bmatrix} = \begin{bmatrix} -\cos\alpha & 0 \\ \frac{sin\alpha}{\rho} & -1 \end{bmatrix} \begin{bmatrix} v_F \\ \omega_F \end{bmatrix} + \begin{bmatrix} -\cos\psi & 0 \\ \frac{sin\psi}{\rho} & 0 \end{bmatrix} \begin{bmatrix} v_L \\ \omega_L \end{bmatrix} \tag{4.108}$$

$$\begin{bmatrix} -\cos\alpha & 0 \\ \frac{sin\alpha}{\rho} & -1 \end{bmatrix} \begin{bmatrix} v_F \\ \omega_F \end{bmatrix} = \begin{bmatrix} \dot{\rho} \\ \dot{\alpha} \end{bmatrix} - \begin{bmatrix} -\cos\psi & 0 \\ \frac{sin\psi}{\rho} & 0 \end{bmatrix} \begin{bmatrix} v_L \\ \omega_L \end{bmatrix} \tag{4.109}$$

$$\begin{bmatrix} v_F \\ \omega_F \end{bmatrix} = \begin{bmatrix} -\cos\alpha & 0 \\ \frac{sin\alpha}{\rho} & -1 \end{bmatrix}^{-1} \left(\begin{bmatrix} \dot{\rho} \\ \dot{\alpha} \end{bmatrix} - \begin{bmatrix} -\cos\psi & 0 \\ \frac{sin\psi}{\rho} & 0 \end{bmatrix} \begin{bmatrix} v_L \\ \omega_L \end{bmatrix} \right) \tag{4.110}$$

$$\begin{bmatrix} v_F \\ \omega_F \end{bmatrix} = \begin{bmatrix} -\frac{1}{\cos\alpha} & 0 \\ -\frac{\tan\alpha}{\rho} & -1 \end{bmatrix} \left(\begin{bmatrix} \dot{\rho} \\ \dot{\alpha} \end{bmatrix} - \begin{bmatrix} -\cos\psi & 0 \\ \frac{sin\psi}{\rho} & 0 \end{bmatrix} \begin{bmatrix} v_L \\ \omega_L \end{bmatrix} \right) \tag{4.111}$$

Thus, the follower velocity can be calculated based on the leader velocity and angular velocity, and distance and angle variables ρ and α

$$\begin{bmatrix} v_F \\ \omega_F \end{bmatrix} = \begin{bmatrix} \frac{k}{\cos\alpha} & 0 \\ \frac{k\tan\alpha}{\rho} & k \end{bmatrix} \begin{bmatrix} \rho - \rho_d \\ \alpha - \alpha_d \end{bmatrix} + \begin{bmatrix} -\frac{\cos\psi}{\cos\alpha} & 0 \\ -\frac{\tan\alpha\cos\psi}{\rho} + \frac{\sin\psi}{\rho} & 0 \end{bmatrix} \begin{bmatrix} v_L \\ \omega_L \end{bmatrix} \tag{4.112}$$

4.3 Self-Organizing Group Formations using the Velocity Potential Method

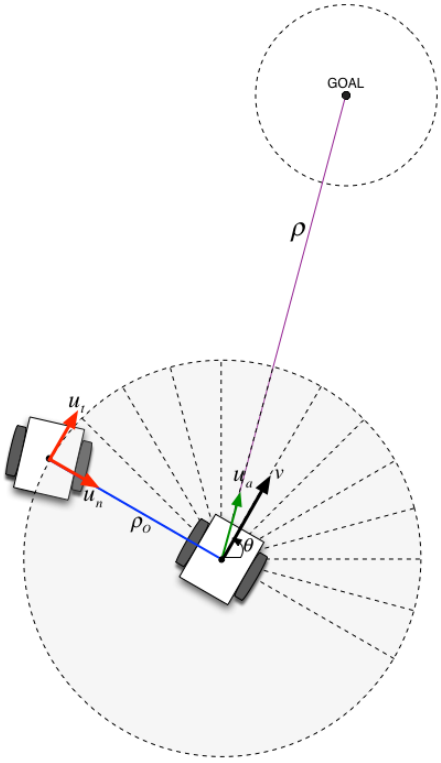

Figure 4.23: Self-organizing collision avoidance

In the self-organizing formation, we will be expanding the velocity potential flow method to handle multiple vehicles moving as a group. Figure 4.23 shows the inter-robot interaction when a robot enters into the sensor radius of another robot. The robot treats the neighbor robot as an obstacle and determines appropriate normal and tangential velocities to navigate around the neighbor robot.

The self-organizing velocity potential algorithm will be designed to be scalable to accommodate any number of robots, from small to large groups.

Chapter 5

Hardware Architecture

The WiRobot X80 platform from Dr. Robot Inc. is a differential drive mobile robot that is designed to provide a user friendly programming environment for hobbyists, students, and researchers. The X80 platform consists of actuators, sensors, and processors to facilitate autonomous robot motion. The X80 system allows developers to quickly test motion algorithms for multi-agent networked robots

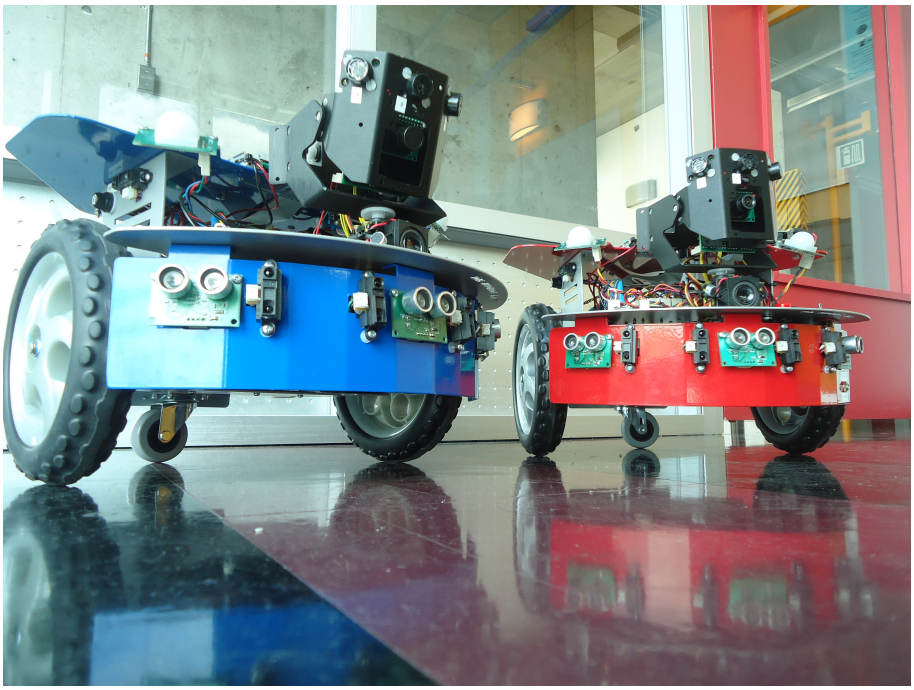

Figure 5.1: X80 mobile robots

This chapter describes all of the hardware components on the X80 mobile robot platform. Section 5.1 gives an overview of the X80 platform, its geometry, and design. Section 5.2 describes the various sensors on the X80 unit. Section 5.3 discusses the actuators for the robot, two 12V DC motors. Section 5.4 outlines the power supply for the robot. Section 5.5 describes the networking setup that enables a personal computer to control all robots via a local WiFi connection. Finally, section 5.6 describes the onboard microcontrollers that dictate low-level control for the mobile robot. Figure 5.1 shows a picture of two X80 mobile robot units from Dr. Robot Inc.

5.1 The X80 Mobile Robot Platform

The X80 platform is a differential drive mobile robot, equipped with sensing and intelligence to achieve autonomous motion. The X80 robots are designed to work in single or multi-robot applications, and operate best in flat terrain environments. The robots are fast, strong, lightweight, and nimble.

Figure 5.2[63] shows a CAD drawing of the front and back view of the X80 platform. The figure outlines the various components of the robot including: range sensors (sonar and IR), human sensor, camera, WiFi antenna, and battery location on the robot unit.

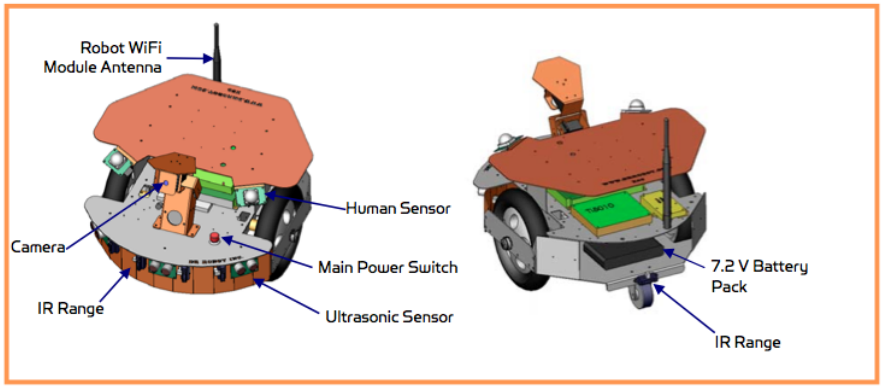

Figure 5.2: The X80 mobile robot and its components

The X80 robot work very well in experimentation in multi-agent systems, since they are designed to operate in a networked setup. Figure 5.3[63] show how three X80 robots all connect to a personal computer (PC) through a wireless network.

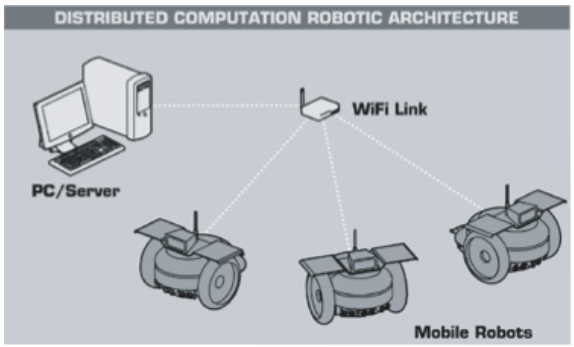

Figure 5.3: Distributed computation and robotic architecture

The WiRobot X80 is designed with a Distributed Computation Robotic Architecture and System (DIRAS) technology, which offloads most of the computation and storage intensive tasks to a personal computer. The PC and X80 robot communicate via a wireless network connection supporting a 100 kbps data communication rate. High-level schemes such as teleoperation, navigation, reasoning, learning, recognition, and image processing routines are programmed and executed on the PC remotely. The block diagram in figure 5.4[63] shows the link between the control program written on the PC and the microcontrollers that executes the program on the robot.

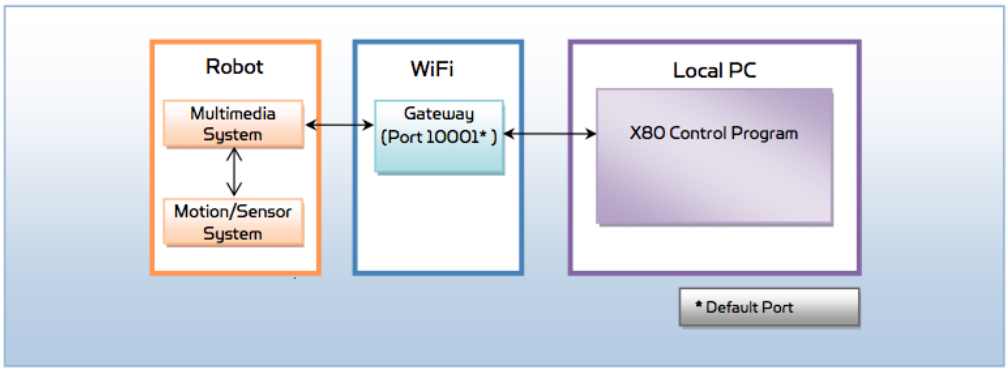

Figure 5.4: Block diagram - robot and local PC network connection

The X80 robot has a top speed of 1 m/s. It is powered by two 12 Volt DC motors that supply 300 oz-inches of torque to the 7 inch wheels. The vehicle is able to move forwards and backwards; when the wheels rotate at equal speeds, in opposite directions, the robot rotates on the spot. Along with the two main wheels, a third castor wheel is added at the rear of the robot to provide added stability. Two high-resolution quadrature encoders, mounted on each wheel, provide high-precision measurement and control of wheel movement. The vehicle is powered by two 3700 mAh nickelmetal hydride (NiMH) batteries.

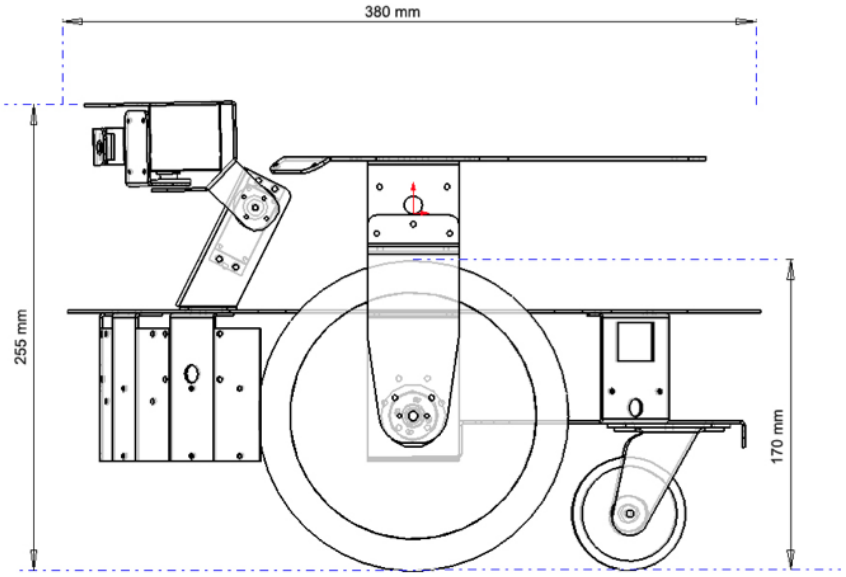

Figure 5.5: Side view of X80 robot with dimensions

The X80 platform measures 38 cm in diameter and 25 cm in height. The platform weighs a total of 3.5 kg, and can support an additional payload of 10 kg. Designers of the X80 made two levels for hardware placement: many of the functional elements are placed on the lower deck, leaving space on the upper deck to carry additional devices such as a laptop. Figure 5.5[63] shows a side view of the X80 mobile robot platform along with its dimensions.

5.2 Sensors

Sensors are the eyes and ears of the mobile robot. They are crucial to the operation of autonomous robots in unknown and dynamic environments, where complete a priori information is impossible to generate before the robot mission. This is especially the case in multi-robot experiments, where the robots must navigate around obstace and simultaneously avoid collisions with each other.

The X80 robot has a series of exteroceptive sensors that acquire information from the robot's surrounding environment. These sensors can be characterized as either passive or active. Passive sensors measure ambient environmental energy entering the sensor. While active sensors emit energy into the environment, and then measure the environmental reaction. The passive sensors on the X80 platform include: human sensors, camera, microphone, and a temperature sensor. Furthermore, the active sensors on the X80 include: ultrasonic range sensors, and infrared range sensors. The X80 robot also has proprioceptive sensors that measure internal values of the robot unit. The X80's proprioceptive sensors include: a tilt sensor to measure robot inclination, and quadrature encoders to measure the vehicle's speed and position.

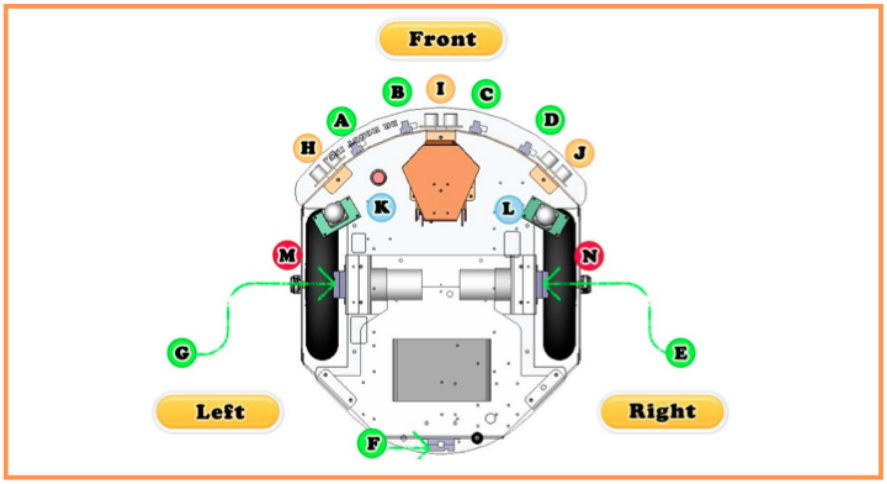

Figure 5.6: X80 top view sensor locations

Figure 5.6[63] shows a top view of the X80 unit, along with the positions of the ultrasonic range sensors, infrared range sensors, human sensors, and quadrature encoders. For our platform, three extra ultrasonic range sensors were installed at the rear of the X80 unit, at the left rear, middle rear, and right rear positions. Table 5.1[63] list the sensor module associated with the letters marked in figure 5.6.

Sensor Module	**Location**
Ultrasonic 1	H - Left front
Ultrasonic 2	I - Middle front
Ultrasonic 3	J - Right front
Human Sensor 1	K - Left front
Human Sensor 2	L - Right front
Infrared Range Sensor 1	A - Front left
Infrared Range Sensor 2	B - Front middle
Infrared Range Sensor 3	C - Front middle
Infrared Range Sensor 4	D - Front right
Infrared Range Sensor 5	E - Right
Infrared Range Sensor 6	F - Rear
Infrared Range Sensor 7	G - Left
Quadrature Encoder 1	M - Left, use channel 1
Quadrature Encoder 2	N - Right, use channel 2

Table 5.1: Sensor Modules

This section will examine all of the sensors on the X80 robot. It will begin with a look at the exteroceptive active sensors on the platform, which are the dominant sensors used in our experimentation. The section will then discuss exteroceptive passive sensors and proprioceptive sensors.

5.2.1 Exteroceptive Sensors - Active Sensors

5.2.1.1 Ultrasonic Range Sensors

Ultrasonic range sensors are used in mobile robotics for map building, obstacle detection, collision avoidance, and general-purpose distance detection. The ultrasonic range sensor module on the X80 transmits packets of ultrasonic pressure waves, and

measures the time it takes for wave packets to reflect and return to the receiver. By detecting the propagation time of the sonic wave between the sensor and the object (if any) in the path of the wave, the controller is able to calculate the distance[53].

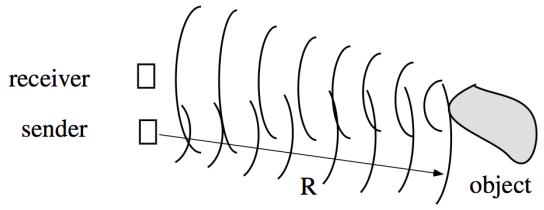

Figure 5.7: Ultrasonic pressure wave reflection

The sonar sensor module transmits packets at a frequency of 40 kHz. The sound wave propagation speed v can be calculated as a function of air temperature T (degrees Celsius) by the following formula:

$$v = 331.5 + 0.6 \cdot T[m/sec] \tag{5.1}$$

The distance to object (in meter) D can be obtained as function of the reflection time t and the velocity v:

$$D = \frac{t \cdot v}{2}[m] \tag{5.2}$$

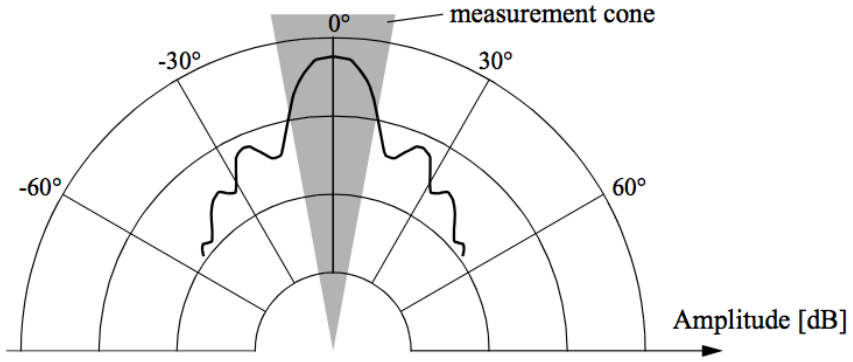

Figure 5.8: Sonar sensor intensity distribution

The ultrasonic range sensor module comes plug-and-play in the WiRobot system, allowing for quick and easy setup and replacement if needed. The sensor can detect ranges from 8 cm to 255 cm, and has a field of view of 10 degrees. Figure 5.8 shows the sensor intensity distribution over the field of view. The ultrasonic range sensor module is shown in figure 5.9, and a view of the sensor installed on the X80 platform is shown in 5.10.

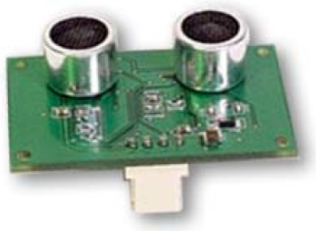

Figure 5.9: Ultrasonic Range Sensor Module

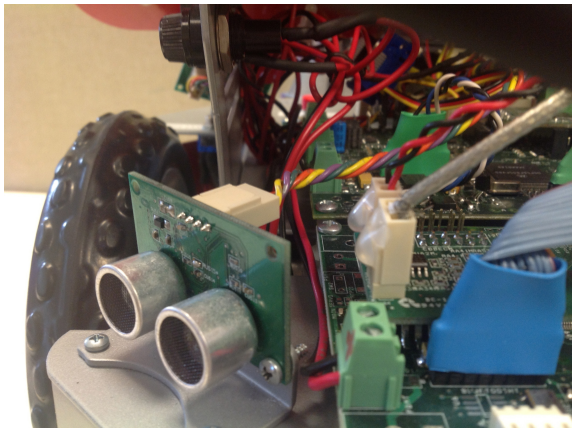

Figure 5.10: Sonar module on the X80 platform

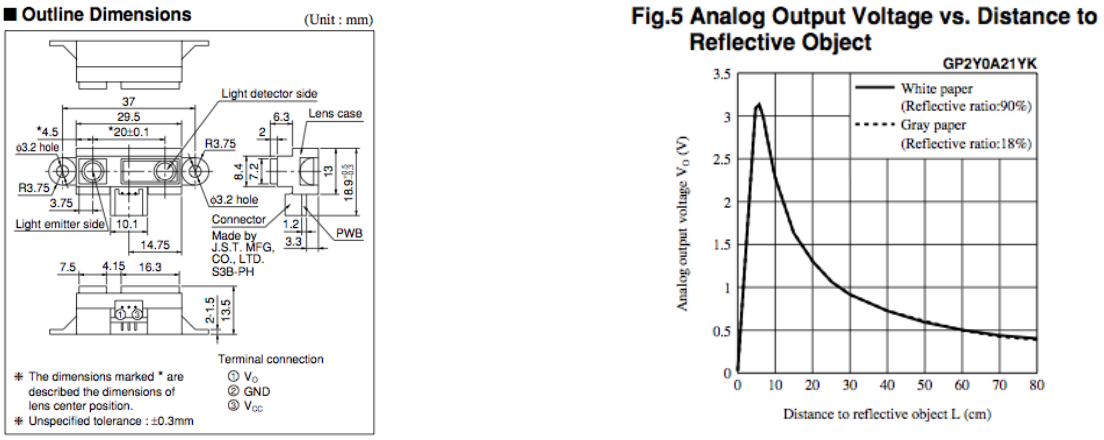
5.2.1.2 Infrared Range Sensors

In mobile robotics, infrared range sensors are generally used as proximity sensors, that detect nearby obstacles. On the X80 platform, the infrared sensor developed by Sharp has a range of 10 cm to 80 cm, and a field of view of 5 degrees. Distance measurements to a reflective object are calculated as a function of the analog output

voltage from the sensor, as seen in figure 5.11b. FIgure 5.12 shows a close-up view of an ultrasonic and two infrared sensor on the front of the X80 unit[63].



(a) (b)

Figure 5.11: (a) Infrared sensor dimensions, and (b) calculating distance as a function of voltage

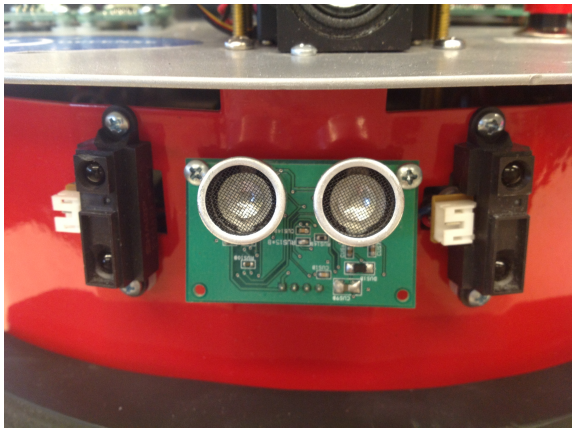


Figure 5.12: Ultrasonic sensor (center) and two infrared sensors (left and right)

5.2.2 Exteroceptive Sensors - Passive Sensors

5.2.2.1 Human Sensor

The human motion sensor module incorporates pyroelectric infrared sensors, to detect infrared energy radiating from a human body. Objects that generate heat also

generate infrared radiation; the infrared radiation generated by a human is strongest at a wavelength of 9.4 micrometers. This sensor is able to detect a human presence in the range of 5 meters. Furthermore, a moving human presence can also be detected, and the direction of movement can be detected in the range of 1.5 meters. Figure 5.13 shows the human sensor module on the X80 robot. Figure 5.14 shows the operation overview of the human sensor and its geometry[63].

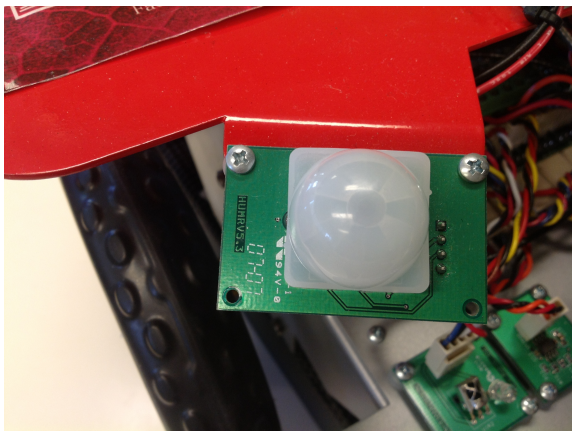

Figure 5.13: Human sensor on the X80

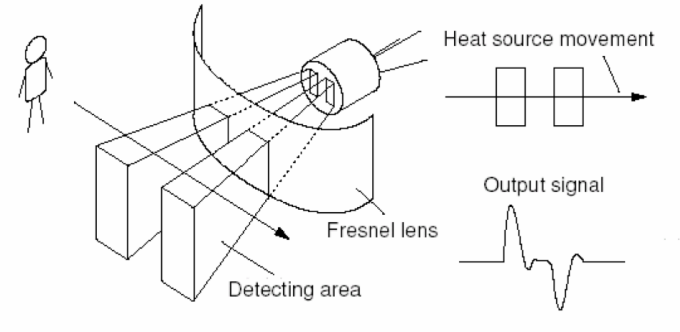
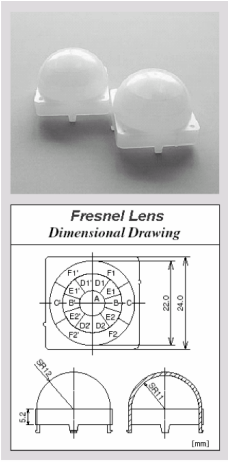


(a)



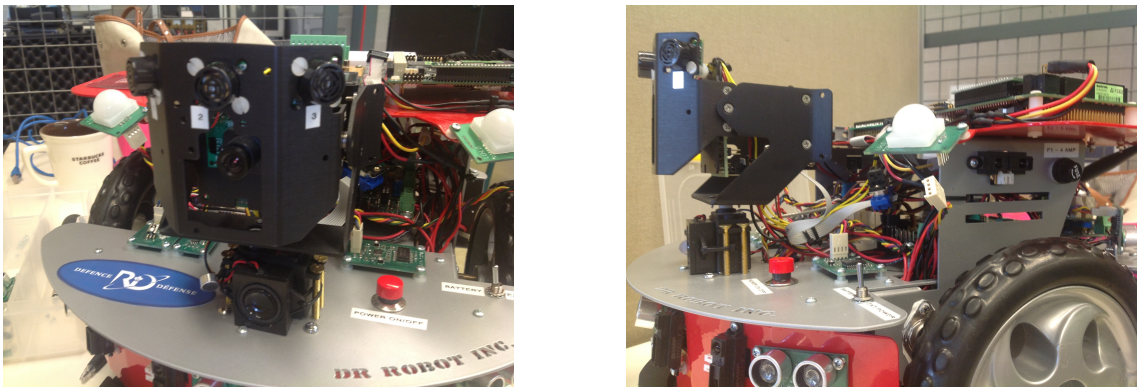
(b)

Figure 5.14: (a) Human sensor operation overview, and (b) human sensor fresnel lens

5.2.2.2 Camera

The X80 mobile robot platform is equipped with a CMUcam3 CMOS (complementary metal-oxide semiconductor) camera. The camera comes complete with an embedded computer vision system; custom C code, for computer vision algorithms, can be developed straight onto the CMUcam3 for optimal processing time. The camera mounting is designed to pan and tilt independently for optimal movement.

The CMUcam3 is a hardware platform coupled with an open source development environment. It is targeted toward users that are already familiar with basic image processing, and who are comfortable working with microcontroller programming. Figure 5.15 shows the front and side view of the CMUcam3 on the X80 platform.



(a) (b)

Figure 5.15: (a) Camera front angle (b) camera side angle

5.2.2.3 Microphone

The Audio Codec and Audio Power Amplifier Module is used as an audio input/output interface in the WiRobot system. The on-board codec provides high resolution signal conversion from digital-to-analog (D/A) and from analog-to-digital (A/D), and with the on-board audio output power amplifier and the microphone preamp in the codec, the external speaker and microphone can be directly connected to the board. Audio Codec and Audio Power Amplifier Module can be used in applications

such as: audio input/output for robots systems, voice and speech recognition, and voice and audio playback. Figure 5.16 shows the microphone location on the X80 robot. Furthermore, figures 5.17[63] and 5.18 display the Audio Codec and Audio Power Amplifier Module and its placement on the X80 robot.

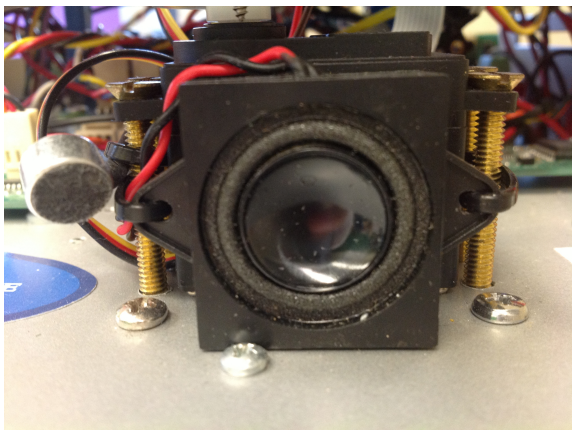


Figure 5.16: Microphone and speaker location on the X80

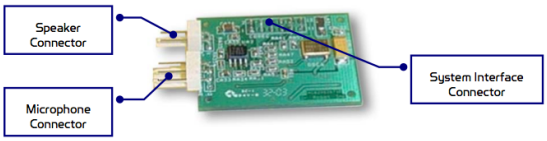

Figure 5.17: Microphone board with labels

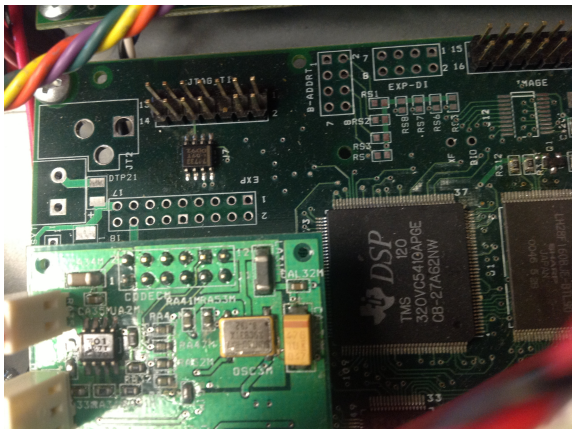

Figure 5.18: Microphone module on the X80 unit

5.2.2.4 Temperature Sensors

The Ambient Temperature Sensor Module is a CMOS temperature sensor that generates a linear voltage signal according to the ambient air temperature. The temperature sensor can be used for high-precision thermal control. Figure 5.19[63] shows the curve used to determine temperature values from voltage inputs. Moreover, figure 5.20 shows the position of the Ambient Temperature Sensor Module on the X80 robot.

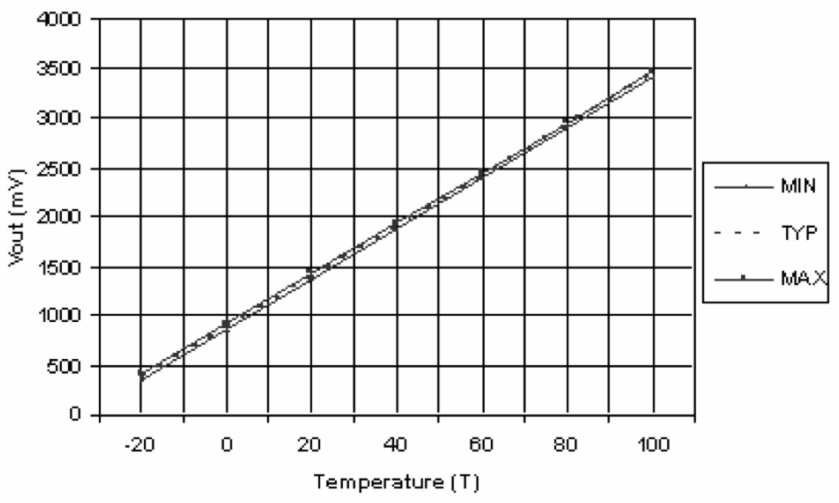

Figure 5.19: Calculating temperature as a function of voltage

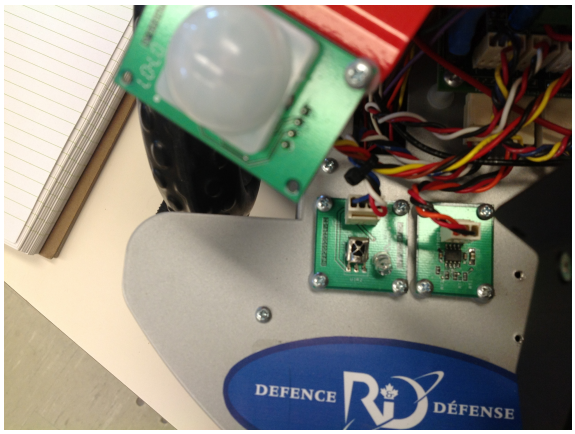

Figure 5.20: IR receiver (left), and temperature sensor (right)

5.2.3 Proprioceptive Sensors

5.2.3.1 Tilt Sensor

The tilt sensor is an inclinometer that measures the incline of the robot while it is moving in the terrain. It measures whether the vehicle is moving up or down a steep incline, or if the vehicle is shifting side to side. Inclinometers are helpful in mobile robotics because alert the user if the robot is inclined too far and could topple over. Figure 5.21 shows the tilt sensor chip on the X80.

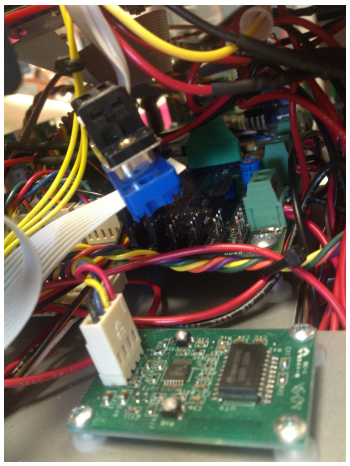

Figure 5.21: Tilt sensor module on the X80

5.2.3.2 Quadrature Encoders

Two high resolution 1200 cycles per revolution (CPR) quadrature encoders are mounted on each wheel to provide measurement and control of wheel movement. Quadrature wheel encoders measure distance by counting the number of ticks produced on a grid passing a barrier. Each quadrature encoder consists of two illumination and detection pairs placed at a 90 degree angle from each other. The addition of the second illumination and detection pair for the quadrature encoder provides significantly more information and improves the resolution of the system.

5.3 Actuators

The X80 is equipped with two wheels, using a differential drive steering model. Differential drive mobile robots offer a large range of mobility, due to their wheel setup. Both wheels are controlled independently from the other, and by coordinating the two different speeds, the robot can perform various maneuvers such as: spin in place, move in a straight line, move in a circular path, and follow prescribed trajectories.

The mobile robot will also be characterized by nonholonomic kinematic constraints that prevent the wheeled robots from moving sideways, perpendicular to the wheel movement, during its motion. Nonholonomic constraints limit the mobility of mobile robots in their workspace, and since sideway motion is prohibited, robots must move around obstacles in a smooth path with an appropriate velocity profile. The two-wheel differential drive mobile robots fare better than their four or six wheel counterparts in working with their nonholonomic motion constraints, since the differential drive robot can slow down and even stop and spin on place when difficult motions are required.

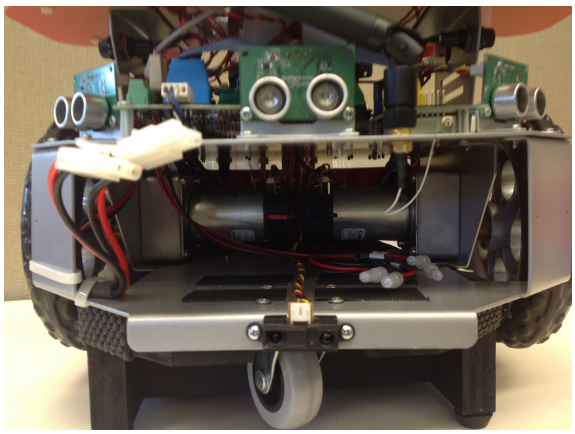

Figure 5.22: Back view of the X80 and its two DC motors

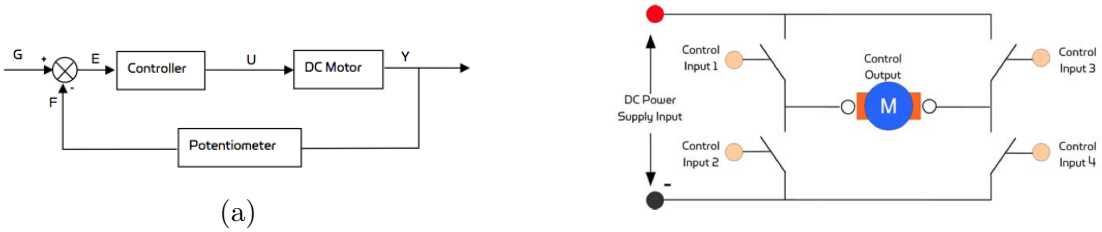
Each wheel is powered by a 12 V DC motor. Figure 5.22 shows the back view of the X80 and a look at the two motors. The DC motors supply 300 oz.inches of

torque to the 7 inch wheels, and yield a top speed 1 m/s.

The DC Motor Driver Module is a low-level controller designed to regulate motor commands in real-time. The controller module functionality is based on the feedback loop of figure 5.23a, and uses a three-channel H-bridge switching power amplifier, figure 5.23b to regulate control commands[63].



(a) (b)

Figure 5.23: (a) Block diagram of the motor control process (b) H-bridge switching device

The DC Motor Driver Module is located on top of and is directly connected to the Sense and Motion Controller board (see section 5.6). Desired velocity outputs from the user are sent from the Sense and Motion Controller board to the DC Motor Driver Module, in order to convert desired motor output to torque values. Furthermore, feedback loops within the module ensure that the torque outputs to the motor stay within a safe working range. Figure 5.24 shows the DC Motor Driver Module, and figure 5.25 shows the controller board location on the X80 robot.

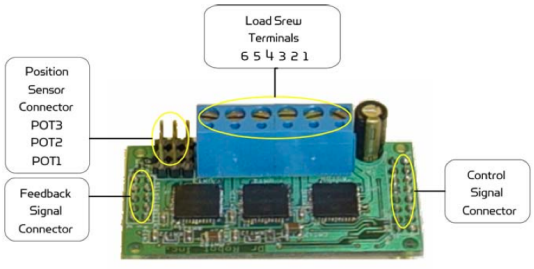


Figure 5.24: DC motor driver module board

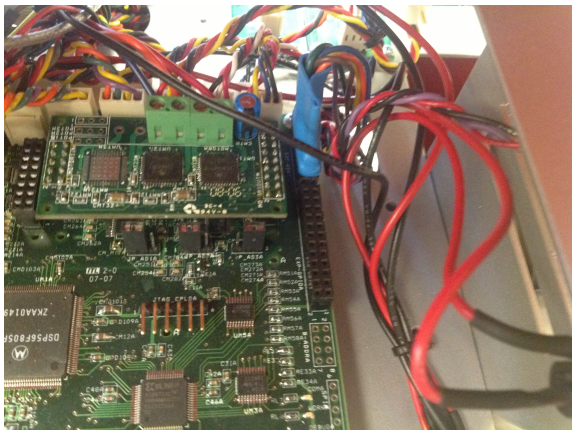

Figure 5.25: DC motor driver module board on the X80

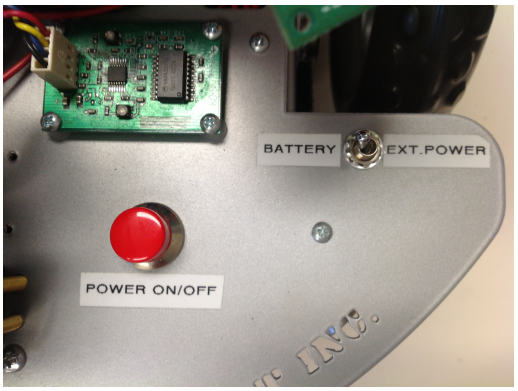
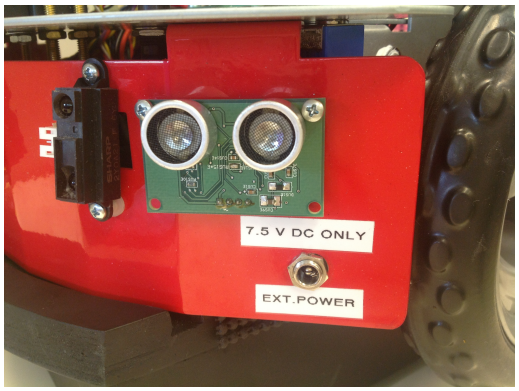
5.4 Power

The X80 mobile robot requires electricity to power its many components. The unit can be powered by plugging it into an electric outlet with a special cable, or it can be powered by two nickel-metal-hydride (NiMH) batteries. Since mobility was a key aspect in our research, batteries were used to power the robot. The NiMH batteries supplied 7.2 V and 3700 mAh to the robot unit. With a full charge, the batteries last approximately 45 minutes.



(a)



(b)

Figure 5.26: (a) Power switch on the X80 (b) external power connection on the X80

Figures 5.26a and 5.26b show the power options and the DC external power port on the X80. Furthermore, figure 5.27 illustrates how the NiMH batteries connect the X80 system, and their location at the rear of the unit.

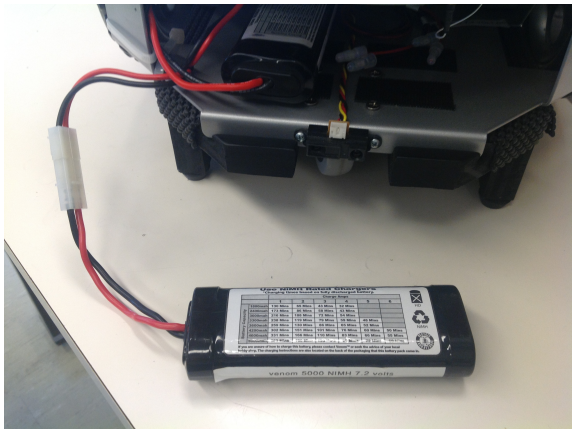


Figure 5.27: Battery connection on the X80

Figure 5.28: Wireless communication between the PC and X80 unit via WiFi

5.5 Networking

Information between the PC and X80 robots travel through a wireless connection. The connection runs at a data communication rate of 100 kbps, and allows for real-time updates to the robot's navigation and formation control parameters. The WiFi system on the X80 has a bandwidth of 11 Mbps and conforms with the IEEE 802.11 wireless standard. The system can upload all sensor data and encoder readings to a PC or server at rates in excess of 10 Hz. Furthermore, the WiFi 802.11 system with

dual serial communication channels, has a max rate of 912.4 Kbps per channel, and supports both UDP and TCP/IP protocol. Streaming audio transmits at a rate of 8 Hz, and streaming video at up to 4 frames per second (fps).

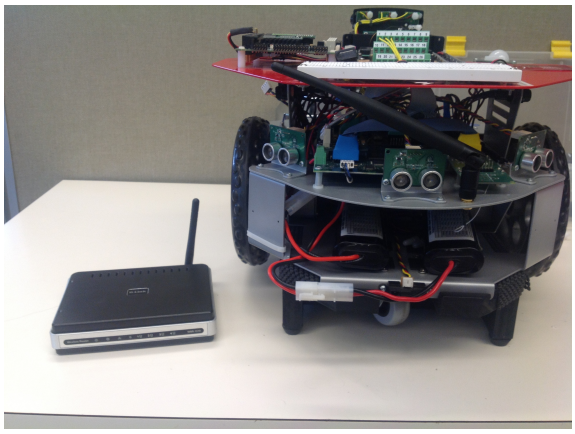

Figure 5.29: X80 robot and router

The networked system provides real-time control and access to the X80 unit without having to program high-level controllers onto its microcontroller. Figure 5.28 illustrates the wireless communication between the PC and X80 unit via WiFi, and figure 5.29 shows a picture of the X80 mobile robot and its router. Finally, figure 5.30 shows the wireless board located on the X80 unit that handles all of the networking commands.

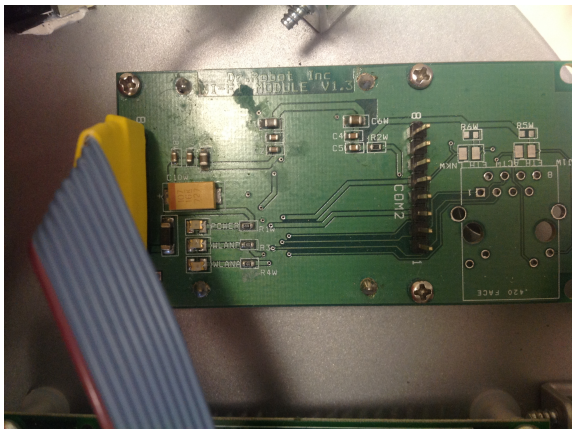

Figure 5.30: Wireless board

5.6 Processors

On the X80, two boards control all of the low-level functionality of the mobile robot: (1) the Sense and Motion Controller, and (2) the Multimedia Controller. The Sense and Motion Controller is the brain of the X80 robot, and as the name suggests, it is responsible for all of the sensing and motion tasks. The Multimedia controller handles all audio and video communications for the robot unit. High-level control for the robot can be communicated via a wireless network, see section 5.5, or it can be programmed onto a microcontroller. On the X80, a Kontron MOPSlcdLX microcontroller is installed for this use.

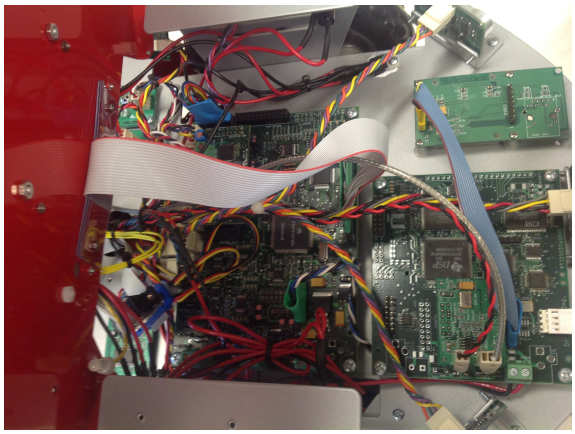

Figure 5.31: Sensing and motion controller board (left), multimedia board (right), and WiFi board (top)

This section will discuss the three boards that handle intelligence for the X80 robot. Figure 5.31 shows the three boards on the lower deck of the X80 unit. Moreover, figure 5.32[63] is a schematic of how the low-level controllers connect to the sensors and other components of the X80 robot.

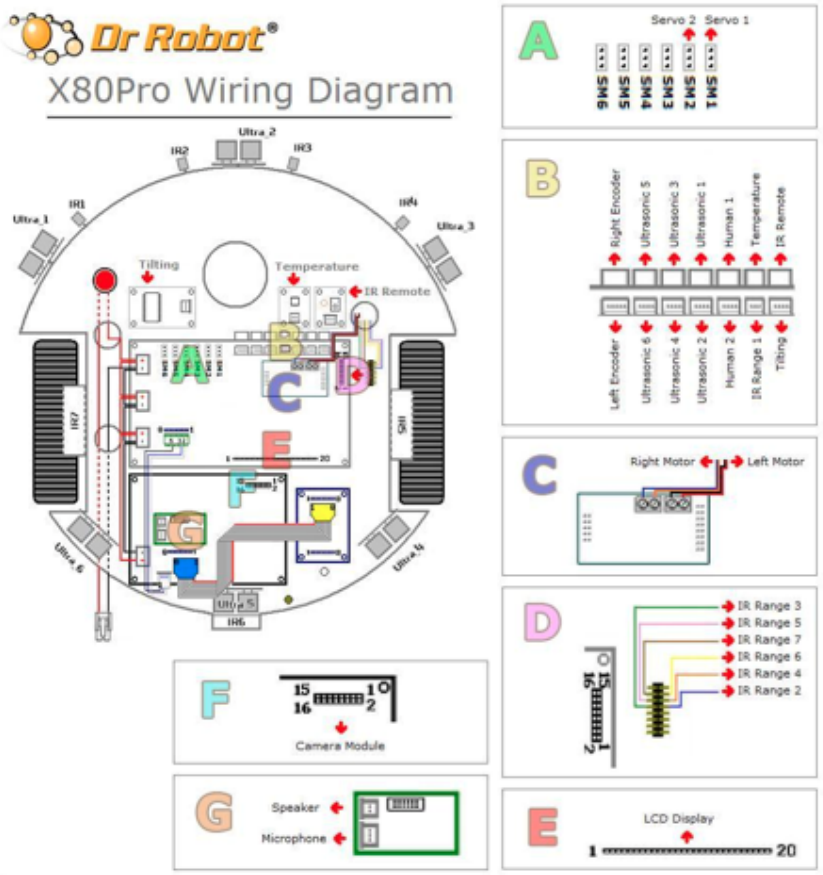

Figure 5.32: X80 wiring diagram

5.6.1 Sensing and Motion Controller

The sensing and motion controller board handles all sensing and actuator commands. It is the hub that collects all information about the robot's state and its local environment. Figure 5.33 shows the location of the sensing and motion controller board on the X80, and a close-up view of how the sensors connect to the board.

The purpose of this unit is gather information about the robot's state to send to the PC to make decisions, then when the PC returns desired velocity values, the sensing and motion controller board converts this information into data that the robot can process and execute. The sensing and motion controller unit is the most important component to the X80 system and is responsible for all of the movement

tasks for the robot. Figure 5.34 shows the sensing and motion controller board and labels all of its key components. Furthermore, figure 5.35 is a block diagram that demonstrates the functionality of the sensing and motion controller unit[63].

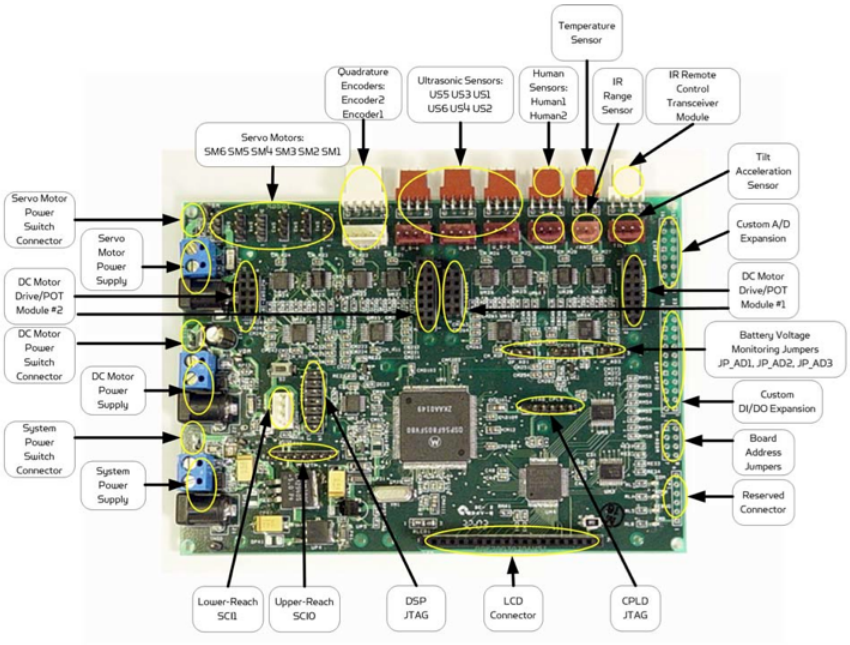

Figure 5.34: Sensing and motion controller board with labels

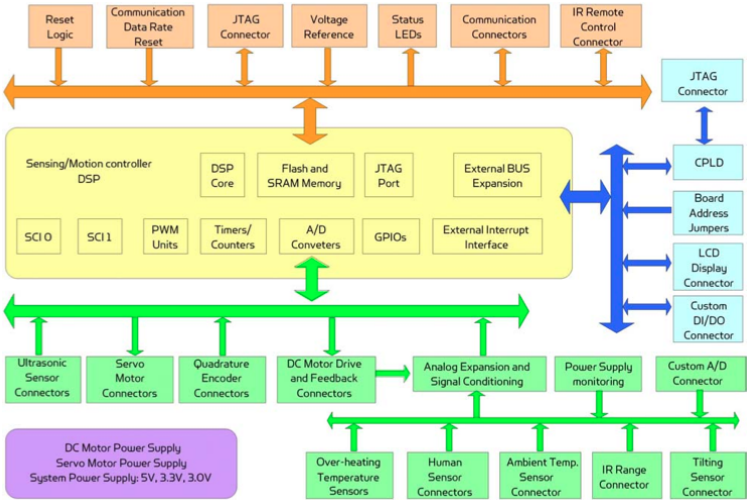

Figure 5.35: Sensing and motion controller block diagram

5.6.2 Multimedia Controller

The multimedia controller handles all of the media elements for the X80. Having a dedicated media controller is especially important for work with camera vision systems, where the processing time can be extensive. Figure 5.36 shows a the position of the multimedia controller on the X80 robot. Figure 5.37 labels the important components of the multimedia controller, and figure 5.38 displays of block diagram of the boards functional elements[63].

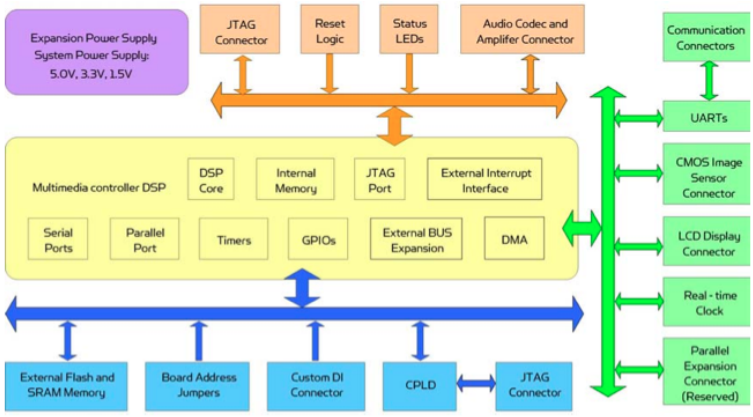

Figure 5.38: Multimedia controller block diagram

5.6.3 Programmable Microcontroller and Additional Inputs

The top deck of the X80 platform is equipped with addition inputs and computation for customized implementations. The Kontron programmable microcontroller lets users add high-level control schemes to dictate robot movement directly on the robot. This type of implementation is desirable after the testing phase, when controllers are proven to be effective, and faster processing time is required. Programs are written in the C language and are uploaded onto the board. Figure 5.39 shows the microcontroller on the X80 platform, and figure 5.40 shows a block diagram of its

northbridge and southbridge design[63]. Figure 5.41 displays additional inputs on the X80 including a breadboard and DB inputs. An LED screen can also be programmed by the user to output information while conducting experiments. Finally, figure 5.42 shows the joystick that was used in our experiments for teleoperation.

Chapter 6

Software Architecture

The X80 mobile robot is equipped with sensors, actuators, and processors to achieve autonomous motion. Its overall autonomy in dynamic environments is dependent on the successful implementation of high-level navigation controllers, that dictate the motion of the robots in real-time.

This chapter covers the software development required to build formation controllers for the X80 Mobile Robot Platform. Section 6.1 describes the design of the X80 platform, and the software-hardware interface. Section 6.2 goes through the benefits of using a prepackaged software framework for robot development and two popular frameworks are described. Finally, section 6.3 compares the two frameworks, and a framework is selected for the research.

6.1 The Software-Hardware Interface

On the X80 platform, software and hardware work together to steer the robots away from collisions and to keep desired formations throughout their movement. Software controllers can be applied to the X80 platform in one of two ways: (1) controllers are programmed in C and are uploaded directly onto its microcontroller, or (2) controllers are programmed in any modern programming language (C, C++,

C#, Java, Pyton, etc.) and messages are sent via a WiFi connection between your personal computer and the X80 robots. The networked setup of method 2 is an excellent architecture for research and development in robotics. This is the case since it allows for quick and easy testing of controller algorithms, without having to upload the new controller code onto its microcontroller each time a change is made.

In networked setup, robots use their sensors to inspect the environment, and sensor data is sent via WiFi to the personal computer where the navigation algorithm is stored. The computer calculates the linear and angular velocities required for the desired motion, and the message is sent back to the robot via WiFi. The robot then inputs velocity commands into its on-board lower-level controllers and calculates applicable torque values. Finally these torque commands are sent the differential drive motors. This process is repeated over every time step.

The networked setup for robot control is intended for prototyping purposes only, to quickly test if algorithms used in robot simulations have similar results when using the robot platform. For our experiments, the networked setup produced excellent results, with no perceivable time delay. However, for an actual implementation in industry, the first method of directly applying the controller algorithm onto the microcontroller is a more computationally efficient process.

6.2 Software Frameworks

Developing software from scratch to control a system of networked robots is a complex, time consuming, and error-prone task. It is far more beneficial for researchers to take advantage of existing software frameworks, designed for work in robotics, as a starting point to develop navigation controllers. A software framework reduces the time and energy required to program controllers onto robots by simplifying hardware access through the use of a hardware abstraction layer. The hardware abstraction

layer hides details about the robot's hardware by defining generic concepts such as sonar sensor, laser sensor, camera, etc., with each having its own standard interface. The navigation controller then does not need to know the details about any particular hardware component, as long as the component complies with its appropriate interface[5]. The details of making a particular component support the standard interface are handled by the driver, which can be programmed by either the hardware manufacturer or the researcher.

Software frameworks are an excellent tool for robot developers since they are scalable, reusable, efficient, fault-tolerant, and as projects gets larger the code can grow with it. Complex robotic applications are all based on frameworks, and these frameworks contain common functionality regarding robotic software and support many of the issues programmers would otherwise have to tackle themselves. A software framework improves the development process and lets developers focus their work on high-level programming to implement movement algorithms.

There are many software frameworks on the market today, and each framework focuses on different aspects such as robustness, efficiency, or ease of use. Currently there is no solution that is clearly superior to all others, so the selection of the software framework depends on the needs of the research laboratory, their budget, and software compliance with specific hardware components. The two most popular frameworks for robot development are Microsoft Robotics Developer Studio and the Player Project.

6.2.1 Microsoft Robotics Developer Studio

Microsoft Robotics Developer Studio (MRDS) is a robot development platform that runs within the Microsoft Visual Studios Integrated Development Environment. MRDS was released in 2008 with the goal of making robot developing easier and more efficient than it had been in the past. Programming robots in MRDS can be

done in one of two ways: (1) using the Microsoft Visual Programming Language, or (2) using the C# programming language.

The Visual Programming Language is a graphical user interface that creates robotic controllers in a visual and tactile way. Controllers are created by connecting blocks that represent hardware components with blocks that represent the logic or movement procedures, in a block diagram type of format[26]. The Visual Programming Language is geared towards hobbyists and students who are learning the robot programming process, to create simple robotic movements.

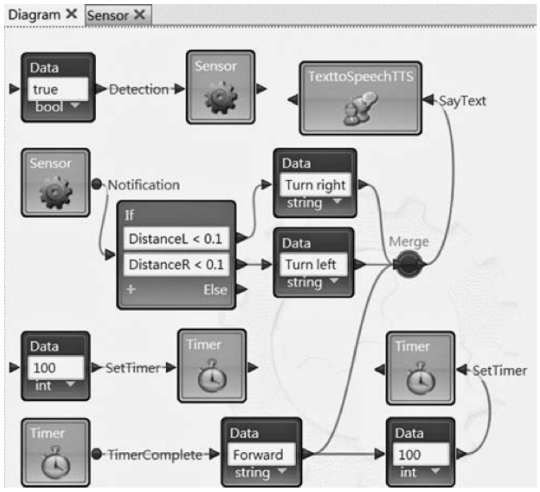

Figure 6.1: Visual programming language screen shot

For our navigation and control algorithms with the X80 robot, the Visual Programming Language did not meet our needs, and the second method, programming in C#, was approached. The developers at Dr. Robot Inc. created several methods and classes in C# that worked directly with the X80 mobile robot in the MRDS environment. Robots applications in MRDS consist of multiple services, which work together to achieve a common task of operating the robot. Services communicate by passing messages back and forth through ports, and manifest files written in XML store the values of hardware components. Concurrency and coordination runtime push services to work in parallel in an asynchronous manner, and allow for

multi-threading type programming[26].

Creating applications with Microsoft Robotics Developer Studio requires understanding of service-oriented architecture, decentralized software services, as well as XML. MRDS programming with the C# language is best suited for industrial large-scale robotics applications.

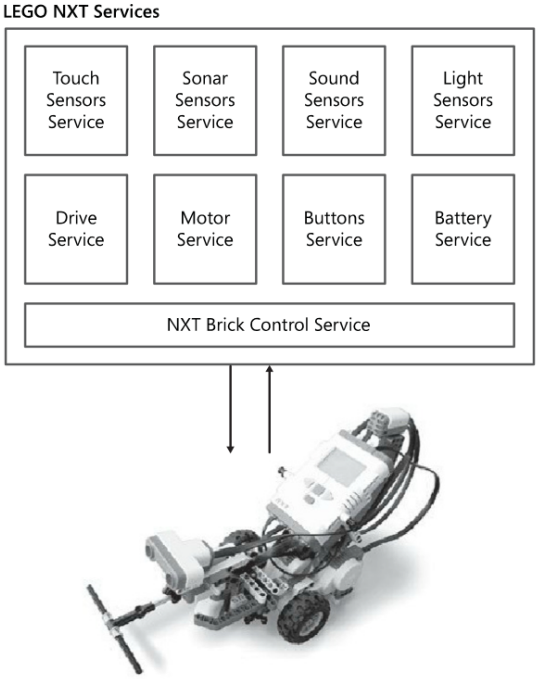

Figure 6.2: LEGO NXT services [26]

6.2.2 The Player Project

The Player Project is an open source robot development environment designed to work on the UNIX platform. Player is most commonly implemented in a Linux based operating system such as Ubuntu, and it has become the de facto standard in the open source robotics community. The software framework was developed in 1999 at the Robotics Research Lab of the University of Southern California to address an internal need for interfacing and simulation for multi-robot systems. In 2001 the project was released under the GNU public license and since then it has

been downloaded more than 100,000 times and is used in many labs and educational institutions worldwide[5].

The Player Projects consists of three major parts: (1) Player, which is the hardware abstraction layer that allows your code to talk to robot hardware components, (2) Stage, a plugin to Player, that creates a two-dimensional simulation of the robots, and (3) Gazebo for generating three-dimensional robot simulations. In general, the Stage simulator is designed to simulate large populations of robots with reasonable accuracy, while the Gazebos 3D simulator is designed with high accuracy and is suited for simulations with a small number of robots[43].

6.2.2.1 Player

Player is a robot device interface that provides a hardware abstraction layer for robotic devices. Player defines a set of standard interfaces, each of which is a specification of the ways that you can interact with some class of devices[62]. For example the position2d interface covers ground-based mobile robots, allowing them to accept commands to make them move and report their state. Many drivers support the position2d interface, and the job of the driver is to make the robot support the standard interface.

Player also provides transport mechanisms that allow data to be exchanged among drivers and control programs that are executing on different machines. The most common transport is the client/server TCP socket-based transport. In this setup, the Player server is executed with a configuration file that defines which drivers to instantiate and how to bind them to hardware. The drivers run inside the player server, often on multiple threads, and the users control program runs as a client to that server.

The Player server provides a convenient API (Application Programming Interface) to a broad range of commercial robots and robotic hardware. Its central

design goals were minimalism and simplicity concerning server and message protocol. Robot controls are implemented as clients of the Player server, and are sent over a network via WiFi. Client programs talk to Player over a TCP socket, reading data from sensors, writing commands to actuators, and configuring devices on the fly.

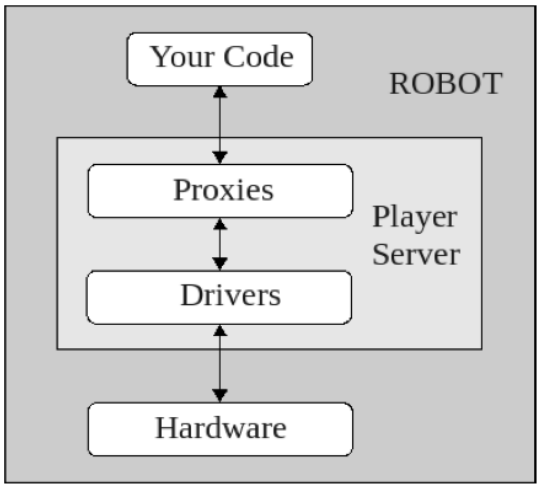

Figure 6.3: Player server [43]

Player is designed to be language and platform independent, and client programs can be run on any machine that has a network connection to the robot, and it can be written in any language that supports TCP sockets. Furthermore, Player makes no assumptions about how you want to structure your robot control programs, and the developer is free to program any way that they like. If you want your client to be a highly concurrent multi-threaded program write it like that, if you like simple read-think-act loop then do that. Client-side libraries are used that hide the internals of the Player message protocol from the developer when programming controllers. The libraries are available in C, C++, Python, Java, LISP, Ruby, and Ada; however C and C++ libraries are the most commonly used.

6.2.2.2 Stage

Stage is a 2D multi-robot simulator from the Player Project. Stage simulates a population of mobile robots, sensors, and objects in a two-dimensional bitmapped environment. Stage is designed to support research into multi-agent autonomous systems, so it provides fairly simple, computationally cheap models of lots of devices, rather than attempting to emulate any device with great fidelity.

There are three ways to implement Stage: (1) a standalone robot simulation program that loads your robot control program from a library that you provide, (2) the Stage plugin for Player provides a population of virtual robots for the Player networked robot interface system, or (3) for writing your own custom simulator inside your own programs. For our use the second implementation, Stage is as a plugin module to Player, is used; this implementation is often called Player/Stage in the robotics community. Users write robot controllers and sensor algorithms as clients to the Player server.

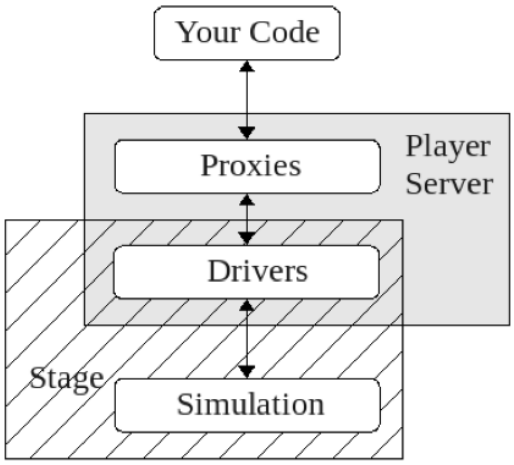

Figure 6.4: Player/Stage [43]

Stage allows for rapid prototyping of controllers designed for real robots. Player clients developed using Stage will work with little or no modification with the real robots, and typically clients cannot tell the difference between the real robot devices

and their simulated equivalents. Since we are working in multi-agent robotic systems, we will only be simulating in Stage and will not work with the 3D simulator Gazebo.

When developing robot controllers in Player/Stage, the methodology is to first start with Stage to simulate how the robot would move in the terrain, and then once the simulation is working as expected, you execute the robot movement with Player. The advantage of using the Player/Stage robot development environment is that as a programmer you can quickly communicate with sensors and actuators without having to worry about how those hardware communications work. Furthermore, the extensive library of methods and classes in C/C++ cover many tasks in robot programming, reducing programming and development time for developers.

6.3 Analysis and Decision: Robot Development Environment

Both Microsoft Robotics Development Studio and Player/Stage were tested with the X80 robot to decide which development environment best suited the research needs. Table 6.1[5] below shows a comparison of the MRDS and Player Project robot frameworks.

Framework	**Microsoft Robotics Developer Studio**	**The Player Project**
Developer	Microsoft Corp.	Robotics Research Lab University of Southern California (USC)
Homepage	www.microsoft.com/robotics	playerstage.sourceforge.net
Platform		
Operating System	Windows	Linux, Mac OSX
General		
Architecture	modular, service-oriented, similar to web services	simple, modular, server/client
Structural Elements	Decentralized System Services (DSS), DSS Nodes	"player servers", "clients", "(virtual) devices"
Runtime Model	event-driven	clents receive data periodically
Development		
Implementation Language	C#	C++
Build Tool	.NET IDE	make
Communication		
Standard Protocol	DSSP, based on SOAP HTTP for web browsers	custom, simple, based on TCP
Data Encoding	XML	XDR
Tools		
Tools Support	Visual Programming Language IDE, Advanced Simulation (3D), Testing	Debugging/Diagnosis, Simulation (2D and 3D)

Table 6.1: Comparison between Microsoft Robotics Developer Studio and Player/Stage

After a thorough analysis it was determined that Player/Stage was a lighter robot development environment, with a significantly reduced development time than the Microsoft alternative. Writing formation controllers in Player/Stage was faster, easier, and simpler than in MRDS. The Player/Stage robot development environment fulfilled all of our research needs, it was an easier platform to work with, and it successfully implemented robot commands from a computer to the X80 robot through a Wi-Fi connection.

Chapter 7

Simulation and Experimental Design

The purpose of the research was to develop formation controllers for a team of mobile robots. Formations add organization and order to the team as they travel through a terrain, and provide a mechanism to avoid collisions. Geometric and self-organizing formation approaches were developed in Chapter 4.

This chapter covers the work done to create simulations and experiments for single and multi-robot systems. Section 7.1 introduces the MATLAB programming language and the steps taken to develop animations of moving robots in a two-dimensional terrain. Section 7.2 explains the Player/Stage relationship, and the steps needed to create animations of multi-robot systems in Stage. Finally, section 7.3 explains the transition from simulations in Player/Stage to robot experiments with the X80.

7.1 MATLAB Simulation Design

MATLAB is a high-level programming language used by scientists and engineers to quickly analyze data, develop algorithms, and create models and applications. MATLAB is an excellent prototyping tool, since the language, toolboxes, and built-in math functions enable users to reach solutions faster than with traditional programming languages such as C/C++ or Java. MATLAB is advantageous for robotic simulations since it provides native support for vector and matrix algebra, enabling fast development and execution of robotic controllers. For our experimental procedure, MATLAB was used as a first step to analyze the feasibility of new navigation algorithms for single and multi-robot cases.

Simulations in MATLAB were created in the MATLAB Editor using the MATLAB programming language. Simulations were executed in the form of animations; animations were used since they could display robot movement and collision avoidance characteristics of the navigation algorithms, and could quickly validate their use. When the MATLAB code was executed, the animation was plotted in the MATLAB Figure window.

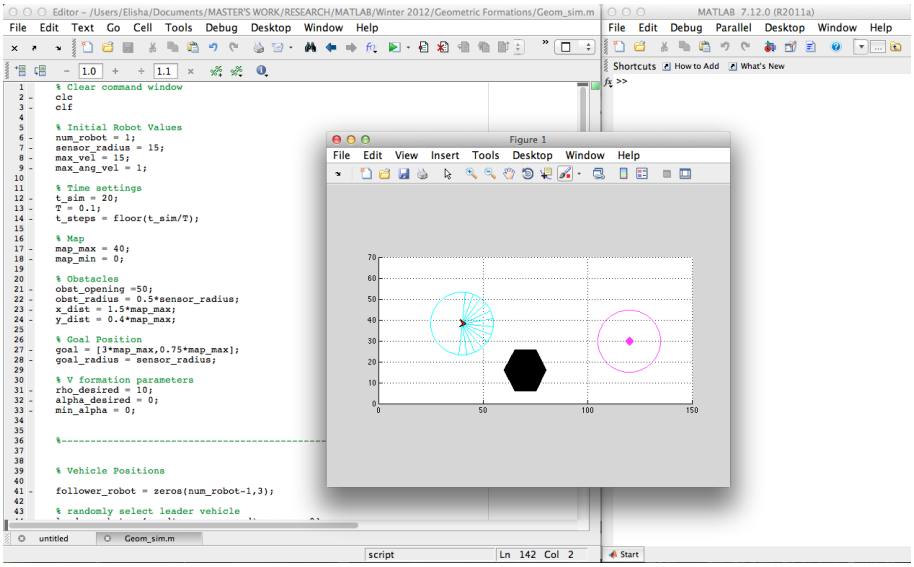

Figure 7.1: Working in the MATLAB Editor to create simulations

7.1.1 MATLAB Simulation Elements

Since simulations in MATLAB were intended to be a first test to see the feasibility of new navigation algorithms, animations were kept as simple as possible. An arrow was used to depict the vehicle's position and orientation in the 2D plane. The robots' x and y position was plotted at each time step in the Cartesian plane, and its yaw angle was depicted by the direction of the arrowhead at each time step. Using the arrow, non-holonomic movement of the mobile robots could easily be visualized.

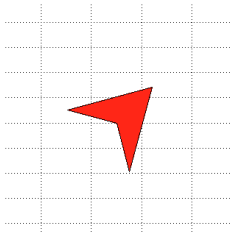

Figure 7.2: Arrow representing the mobile robot's pose in the terrain

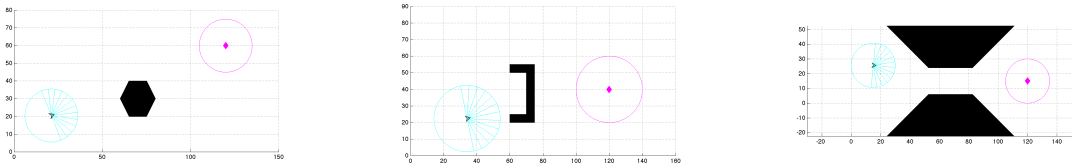
Furthermore, obstacles in the terrain were designed with geometric shapes. Since complex shapes were difficult to draw in MATLAB, all obstacles were represented as polygons and were drawn using tools from MATLABs Graphics toolbox. The obstacles were colored black in all of our simulations



(a) (b) (c)

Figure 7.3: (a) Hexagon shaped obstacle, (b) C-shaped obstacle, c) narrow passage obstacle

Mobile robots use their sensors to analyze the terrain and find obstacles. For the simulations, the sensors were plotted as cyan beams extending from the center of the robot. Each beam was separated by an angle PI/12, and all beams had a

constant beam radius that was defined by the user. A circle joining the outer ends of the beams defined the viewing area of the mobile robot, the area where the robot could see and interact obstacles in the terrain.

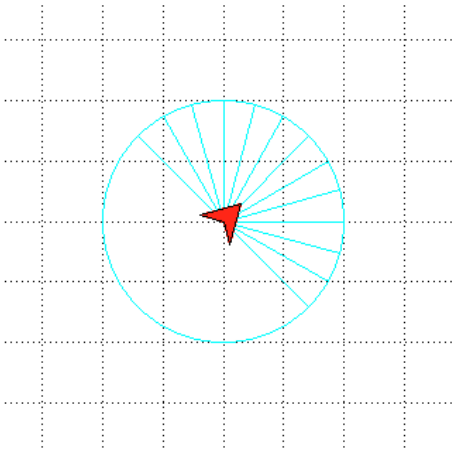


Figure 7.4: Sensor beams around the robot

When an obstacle entered the viewing area of the mobile robot, the intersection of the beam and the obstacle polygon was plotted using commands from MATLABs Mapping Toolbox. In the simulations, the intersection point was plotted with a small red circle, and the beam with the closest intersection point was implemented in the collision avoidance algorithm.

In the terrain, a goal position was plotted using magenta diamond. The simulations were designed to work for a single robot case, and also could easily expand to a multi-robot case. The multi-robot case was designed to incorporate any number of robots set by the user. At the beginning of all simulations, the robots were randomly positioned in the terrain, at random x, y, and theta values. Randomly generated initial positions were important to better test the validity navigation algorithms with difficult robot orientations.

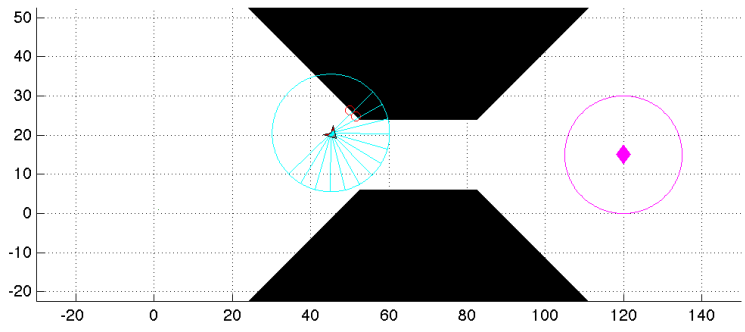

Figure 7.5: Beam intersection with an obstacle

Finally, the user had control over several constant constraints in the simulation. The user could modify the size of the terrain, simulation time and time steps, number of robots, sensor beam radius, the maximum velocity and angular velocity of the robots, the position and shape of the obstacles in the terrain, and the goal position in the terrain Simulations are executed by pressing the 'Run' command in the Editor window.

7.2 Stage Simulation Design

The purpose of the MATLAB simulations at the beginning of the research was to test the validity of our navigation and formation algorithms. Once we were satisfied with the MATLAB simulation results for the single and multi-robot cases, we moved forward to create simulations in Player/Stage. Stage simulations take into account the exact geometry of the X80 mobile robot, along with sensor locations, sensor limits, and actuator variables. Stage simulations allowed for more interesting and

complex terrains. This was the case since drawings made in a paint program could be added to the world file, making far more realistic terrains for the simulated robots to move in. Stage simulations were an intermediary step between MATLAB simulations and the X80 experiments, to see how the robots would behave with the navigation and formation control algorithm. Simulations in Stage gave a more accurate picture of the robot movement with its actual hardware constraints, and showed how the robots interacted with each other in complex terrains with many obstacles.

7.2.1 Player/Stage Implementation

Player and Stage work together to operate mobile robots from a Unix based operating system such as Linux or Mac. Player is a hardware abstraction layer that provides access to the robots sensors and actuators for real robot testing. Stage is a 2-dimensional simulation software. Within stage you set up the geometry of the robot, what sensors are onboard, where the sensors are located on the robot, and any obstacles situated in its environment.

The largest benefit of using the Player and Stage software is the quick and easy transition from simulation to testing. Control of the robot movement is achieved with a C++ file that access values from sensor data and apply actuator control. The controller runs in parallel to Player, and is implemented in the same manner in either simulation or testing mode.

In Player/Stage there are three main types of files that you work with. Firstly, the World file describes the simulated world that the robot moves in, and any items within the world like obstacles. Moreover, the Configuration file gives player information about the robot, and tells Player what drivers it needs to access in order to interact with the sensors and actuators on the robot. If you are creating a simulation, the configuration file points to the Stage driver. Finally, in order to move the

robot and apply any type of intelligence, a controller file is programmed in either C or C++. The controller file includes the Player C/C++ library, it uses player commands to access input sensor data, and the file can also output commands to actuators. The C/C++ code is compiled and built, and the executable file works in conjunction with the configuration file to move the robot.

7.2.2 The World File

The first step in developing a Stage simulation is to define the world that the robot lives in. Firstly, the world file described the details about the robot geometry, its exact size, and parameters. Table 7.1 describes the center of gravity, mass, and volume parameters of the X80 robot. Furthermore, table 7.2 details how the robots were drawn in the world file. The X80 was split up into various sections: the back, the middle, the front, and the left and right wheels. Each point on on the geometry was plotted to create a polygon, and the interior of the polygon was colored. Finally, figure 7.6 shows the final drawing of the X80 robot in the world based on the geometric parameters in table 7.2.

General Robot Parameters	**Values**
Center of Gravity [x, y, z] in meters	[0.0, 0.025, 0.0]
Mass in kg	3.5
Volume [x, y, z] in meters	[0.33, 0.36, 0.26]

Table 7.1: Robot parameters in the World

Robot Section	**Number of Points**	**Coordinates in the x-y Plane in meters** $[x, y]$	**Coordinates in the z-plane** in meters $[z_{min}, z_{max}]$	**Color**
Red back	6	point[0] [0.0, 0.21] point[1] [0.0, 0.12] point[2] [0.08, 0.05] point[3] [0.25, 0.05] point[4] [0.33, 0.12] point[5] [0.33, 0.21]	[0.17, 0.26]	Red
Middle gray rectangle	4	point[0] [0.06, 0.21] point[1] [0.27, 0.21] point[2] [0.27, 0.26] point[3] [0.06, 0.26]	[0.085, 0.165]	Gray
Front gray arc	11	point[0] [0.0, 0.29] point[1] [0.0, 0.26] point[2] [0.33, 0.26] point[3] [0.33, 0.29] point[4] [0.28, 0.33] point[5] [0.25, 0.34] point[6] [0.22, 0.35] point[7] [0.165, 0.36] point[8] [0.11, 0.35] point[9] [0.08, 0.34] point[10] [0.05, 0.33]	[0.085, 0.165]	Gray
Left wheel	4	point[0] [0.0, 0.09] point[0] [0.03, 0.09] point[2] [0.03, 0.26] point[3] [0.0, 0.26]	[0, 0.17]	Black
Right wheel	4	point[0] [0.3, 0.09] point[1] [0.33, 0.09] point[2] [0.33, 0.26] point[3] [0.3, 0.26]	[0, 0.17]	Black

Table 7.2: Drawing an exact copy of the X80 robot geometry in Stage

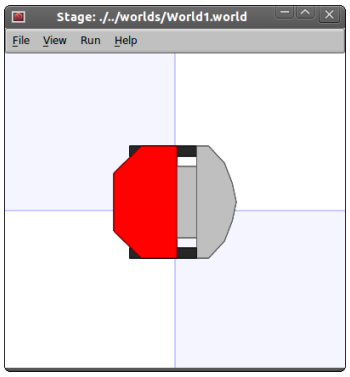

Figure 7.6: X80 simulated robot in Stage

The next step in the design of the world file is to tell Stage where the sensors are located on the robot unit. Tables 7.3, 7.4, 7.5, and 7.6, show the properties and positions of the sonar and infrared range sensors on the X80 robot. Sensor positions were included in the world file, and figure 7.7 shows a final picture of the X80 with its range sensors in the world file.

Sonar Sensor Properties	**Values**
Number of sonar sensors	6
Field of view of each transducer [range min, range max, view angle] in meters and degrees	$[0.08, 2.55, 10°]$
Size of each transducer $[x_{size}, y_{size}]$ in meters	$[0.05, 0.02]$

Table 7.3: Sonar parameters for the X80 robot

Sonar Position	**Coordinates [x, y, yaw angle] in meters and degrees**
Front left	$[0.14, 0.14, 45°]$
Front center	$[0.19, 0.0, 0°]$
Front right	$[0.14, -0.14, -45°]$
Back right	$[-0.12, -0.125, -135°]$
Back center	$[-0.18, 0.0, 180°]$
Back left	$[-0.12, 0.125, 135°]$

Table 7.4: IR position coordinates on the X80

IR Sensor Properties	Values
Number of infrared sensors	7
Field of view of each transducer [range min, range max, view angle] in meters and degrees	$[0.1, 0.8, 5°]$
Size of each transducer $[x_{size}, y_{size}]$ in meters	$[0.01, 0.03]$

Table 7.5: Infrared parameters for the X80 robot

IR Position	Coordinates [x, y, yaw angle] in meters and degrees
Front left	$[0.16, 0.10, 40°]$
Front left center	$[0.17, 0.04, 10°]$
Front right center	$[0.17, -0.04, -10°]$
Front right	$[0.16, -0.10, -40°]$
Right	$[0.0, -0.12, -90°]$
Rear	$[-0.18, 0.0, 180°]$
Left	$[0.0, 0.12, 90°]$

Table 7.6: Infrared position coordinates on the X80

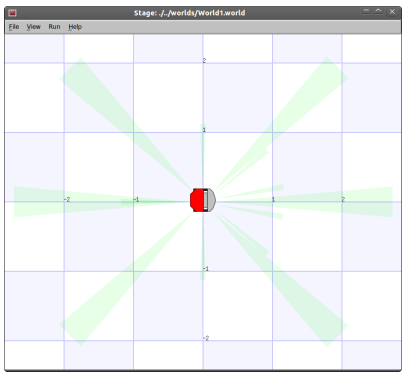

Figure 7.7: X80 with sonar and IR beams simulated robot in Stage

Finally the last step in creating the world file is to provide information about obstacles in the environment. Terrains could be generated in two ways: (1) simple geometric shapes, like rectangles and polygons could be drawn using drawing commands in the world file, or (2) terrains could be uploaded from a drawing file with a Portable Network Graphic (.png) or a Bitmap Image File (.bmp). For our simulations, image files of the terrain were saved in the .png file format. Figure 7.8 shows a complex environment that can be used to test the X80 controllers.

Figure 7.8: A possible simulation environment in Stage

7.2.3 The Configuration File

Once the robot parameters and the terrain environment were defined in the world file, a configuration file was created to begin the simulation. The configuration file lists the simulation plugin "stageplugin", the world file associated with the simulation, and the port (6665) for the position and sensor proxies. The code below is used to create a very simple simulation for a single robot. See the appendix section on developing a simple simulation in Stage for further details.

```
# STAGE DRIVER ------

driver
(
        name "stage"
        provides ["simulation:0"]
        plugin "stageplugin"
        worldfile "AutoWorldFiles/robot1.world"
)

# X80 DRIVERS ------

driver
(
        name "stage"
        provides ["6665:position2d:0" "6665:sonar:0" "6665:sonar:1"]
        model "robot1"
)
```

7.2.4 Developing Robot Controllers in C++

The configuration and world files in Player/Stage define the static parameters of the robot: its geometry, sensor parameters, and initial position in the world. When the configuration file is executed, the robot is displayed at its initial position, but it cannot move. In order to move the robot around its terrain to view its navigation and collision avoidance algorithms, a controller file must first be made to tell the robot how to move. Controllers in Player/Stage are written in C/C++. The first step in the process was to find an Integrated Development Environment (IDE) to program the C++ code in the Ubuntu Operating System. Two popular open source IDEs were investigated: Eclipse and Code::Blocks. After testing both IDEs with the PlayerC++ tools, it was found that Eclipse integrated best with the Player/Stage libraries, and was the easiest IDE to work with for our experiments.

The next step in the process was to take the MATLAB navigation and formation controllers and to write them in C++ in the Eclipse IDE. The C++ code was linked to the PlayerC++ library in order to utilize the Player commands. The following section outlines the methods and attributes of the Player classes used in our simulations.

The PlayerC++ library is a massive library of popular robot commands used by in academia. The library consists of classes that command manipulator and mobile robot actuators and sensors. In this section, only the PlayerC++ proxies that were used in the experiments with the X80 mobile robot will be described.

The PlayerClient is used for communicating with the Player server. Each robot is assigned its own PlayerClient at the beginning of the program to connect to the Player server, and each PlayerClient has a port number associated with it. In Player/Stage the port numbers start at port 6665 for the first robot, then increments by one for each additional robot (for example, the second robot will occupy port 6666, the third robot will occupy port 6667, etc.) Contained within the PlayerClient

object are methods for changing the connection parameters and obtaining access to devices.

The Position2dProxy class is used to control mobile robots in a 2D plane. Using the methods within this class you can get the current pose of the robot, and set the speed of the vehicle. In our experiments, velocity and angular velocity values were calculated from our algorithms. These velocity commands were executed in our Player/Stage simulation using the SetSpeed() method in the Position2dProxy class.

The SonarProxy is used to control sonar devices. In our experiments, both the sonar and infrared sensors were accessed using SonarProxy commands. The sonar interface provides access to a collection of fixed range sensors, and outputs the values as an array. Range measurements of the sensors allow the mobile robots to see and understand its environment in order to avoid collisions.

All of the functions associated with the PlayerClient, Position2dProxy, and SonarProxy are listed in Appendix C

7.2.5 Running a Stage Simulation

To run a simulation in Player/Stage you use the terminal window in Ubuntu. If the configuration file for the experiment was saved as sim.cfg, find the location of the file in the terminal window and once the folder is accessed use the command

player sim.cfg

The Player command will open a viewer with the terrain and robot described from the sim.cfg configuration and world files. Next, open a second terminal window and search for the C/C++ controller file that was built in Eclipse. If the C/C++ file was save as controller.cpp, Eclipse will debug and build the application. To run the controller, find the location of the executable file, and write the following command in the terminal window.

./controller

After the controller is executed, the robot will move in the environment until you tell it to stop. For our experiments we included the csignal library; methods from this library allow for keyboard inputs to stop the robot prematurely, if necessary, from the terminal window.

7.3 Transitioning from Simulations to Robot Implementation with Player/Stage

To run the navigation and formation control algorithm on the X80 in Player/Stage, it is a simple matter of changing the configuration file. Instead of calling the simulation proxy, player references a plugin specifically designed for the X80 robot called libx80. This plugin is a binary file created through the source code x80.cc that can be found in appendix F. In the configuration file you choose a connection type, in our case a UDP network, and write the IP address of the robot in use: 192.168.0.205. The port and initial pose of the robot are then listed, and sonar and IR filter parameters can be applied. The hardware configuration file for a single robot is shown below.

```
# X80 DRIVER ------------------------------------------------------

driver
(
        name "x80"
        plugin "../player_drivers/X80PlayerPlugin/lib/libx80"
        provides ["6665:position2d:0" "6665:sonar:0" "6665:sonar:1"]
        connection      "udp"
        address "192.168.0.205"
        port            10001                   # for udp only
        pose [0 0 0 0]

        sonar_filter    1.0     # low pass filter smoothing factor, <=
            1.0
        ir_filter       1.0     # low pass filter smoothing factor, <=
            1.0
)
```

Executing the X80 with the control algorithm follows the same procedure as executing the simulated robot. If the configuration file for the experiment was saved as hardware.cfg, find the location of the file in the terminal window and once the folder is accessed use the command

player hardware.cfg

To run the controller, find the location of the executable file, and write the following command in the terminal window.

./controller

After the controller is executed, the X80 robot will move in the room until you manually tell it to stop, or the robot reaches its destination.

Chapter 8

Results for Single Robot Experiments

The purpose of the research was to develop formation controllers for a team of autonomous mobile robots. Collision avoidance was a main requirement in our research objectives; the team was expected to travel together through a terrain, while avoiding collisions with obstacles in the environment. The first stage of our research was to develop a navigation strategy for the robots to avoid static obstacles in the terrain. The following chapter describes the results for navigation with a single robot using the velocity potential method detailed in Chapter 4.

Section 8.1 gives a quick overview of the flowchart symbols used to describe the methodology for our programming code. Sections 8.2 and 8.3 describe the simulation algorithm and simulation results for the single robot experiments. Finally, sections 8.4 and 8.5 describe the experimental algorithm and results for our work with the X80 mobile robot.

8.1 Flowchart Symbols

In our work, high-level controllers for collision avoidance and formation control were programmed in the MATLAB and C++ programming languages. Due to the length of the code for each experiment, it was not practical to insert the programming work in the results sections for chapters 8, 9, and 10. Instead, flowcharts are used to visually display the methodology, and the programming work for each simulation and experiment is listed in the Appendix. Figure 8.1 displays the flowchart symbols that were used in describing our simulation and experimental work.

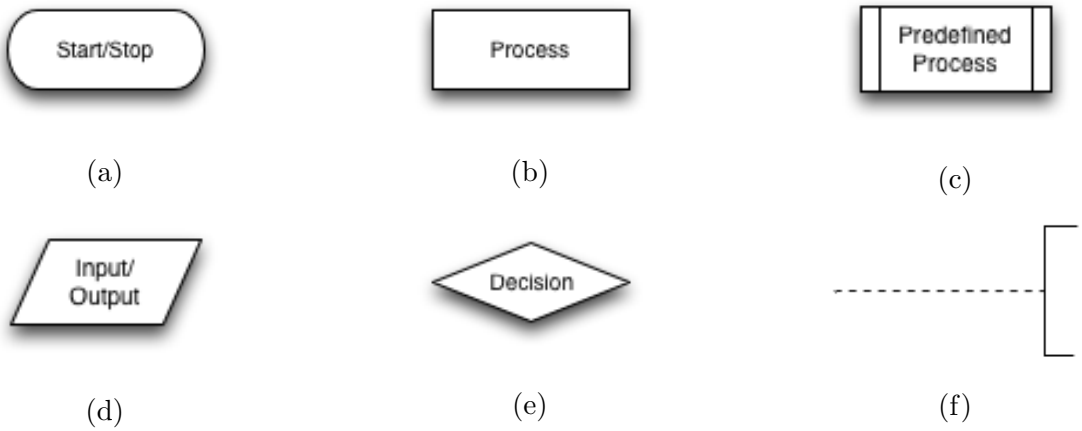

Figure 8.1: Flowchart symbols

Firstly, the Start/Stop terminal symbol 8.1a represents the beginning or end of a procedure or program. Terminals beginning a procedure will contain the name of the procedure, and terminals ending a procedure contain the word EXIT. Secondly, the Process symbol 8.1b represents a processing task within the program. Any data manipulation, computation, or movement of data within the program is illustrated using a process symbol. Thirdly, a Predefined Process 8.1c indicates that the instructions to be executed are located elsewhere in the program. In our case, we used the predefined process symbol to keep the code simple, by incorporating functions that separate portions of the code in a separate flow charts. Forthly, the Input/Output process 8.1d is used to indicate that some input or output operation

is being performed. Input operations include reading files and interacting with the user. Output operations include writing files and displaying information. Fifthly, the Decision symbol 8.1e represents a point in the program where the logic flow will follow one of the two paths depending on a given situation. Finally, the Annotation symbol 8.1f is used to comment on a portion of the program in an effort to explain why the program is performing some task. In our work, the annotation symbol is used as a reminder of actions we need to take in initializing our program for execution.

8.2 Simulation Algorithm

Simulations for navigation using the velocity potential method were first carried out in MATLAB using the methodology described in Chapter 7. In this simulation, a single robot navigates through the terrain towards the goal, following an attractive flow field. If the robot senses an obstacle, a spiral vortex is created in the obstacle position, and the flow pushes the robot away from the obstacle. Figure 8.2a shows a flowchart of the main function for the simulation. The main function initializes parameters such: as maximum velocity and angular velocity, sensor radius and goal radius, constants, and map dimensions. Furthermore, it gathers inputs from the user such as the initial robot pose and goal position in the map. The majority of the calculations occur in a loop, figure 8.2b, where robot checks for nearby obstacle, calculates its new pose, and plots the goal, obstacles, and robot pose in the MATLAB figure window.

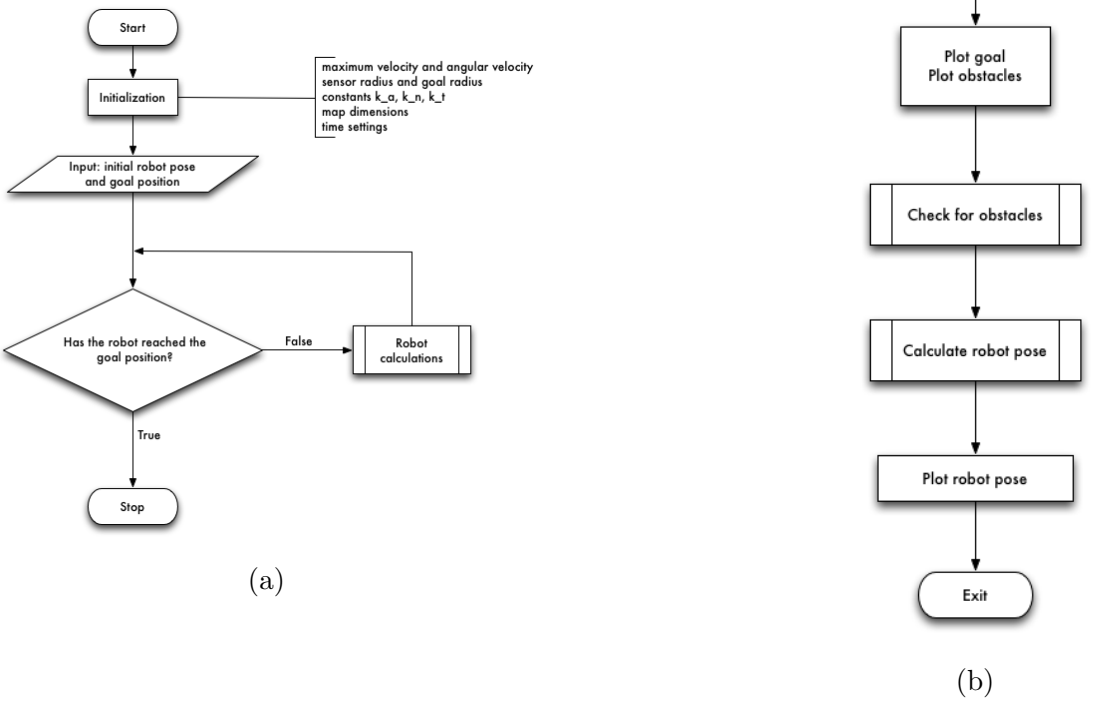

Figure 8.2: (left) main function, (right) robot calculations

The details of the *Check for obstacles* function and *Calculate robot pose* function are explained in figures 8.3a and 8.3b. The *Check for obstacles* function scans the sonar and infrared sensors to see if an obstacle is in range. If an obstacle is in view, the function stores the range and angle measurement for the sensor with the shortest distance to the obstacle. The *Calculate robot pose* function implements the velocity potential method calculations from Chapter 4, and calculates the attractive, repulsive, and resultant velocity and angular velocity of the robot. The full MATLAB program for the single robot simulation can be found in Appendix G.

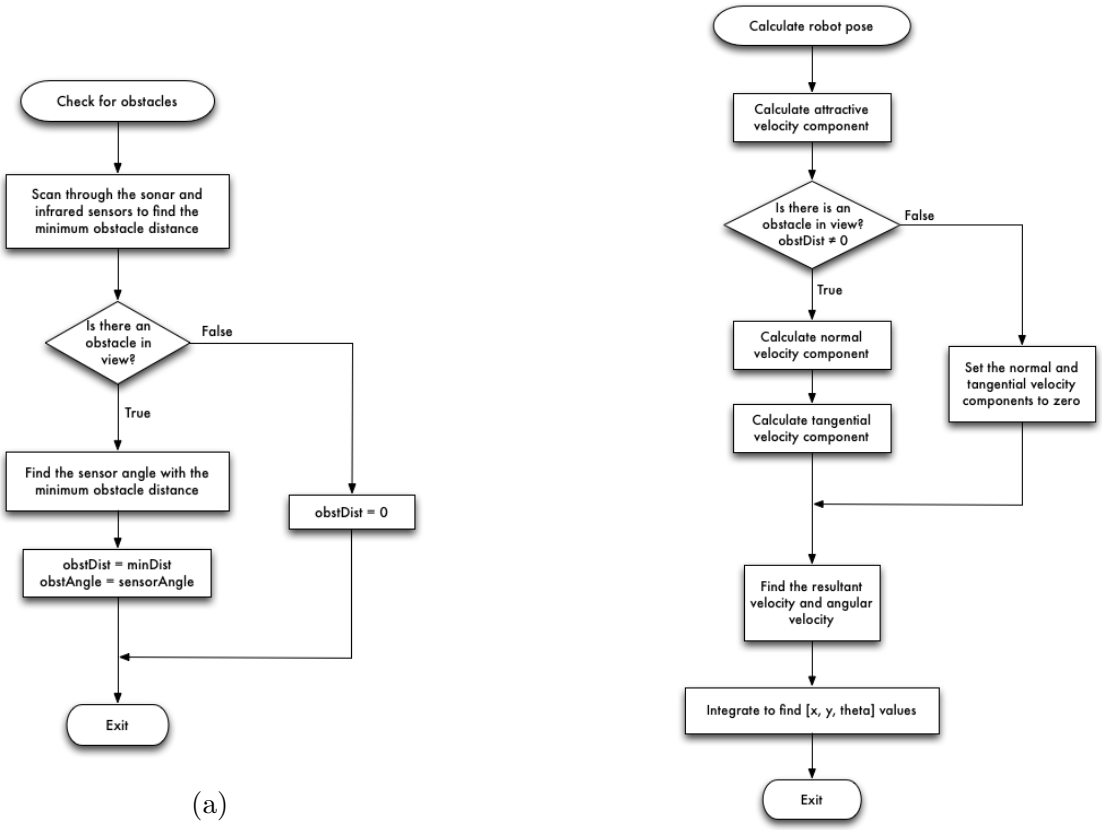

Figure 8.3: (left) check for obstacles, (right) calculate robot pose

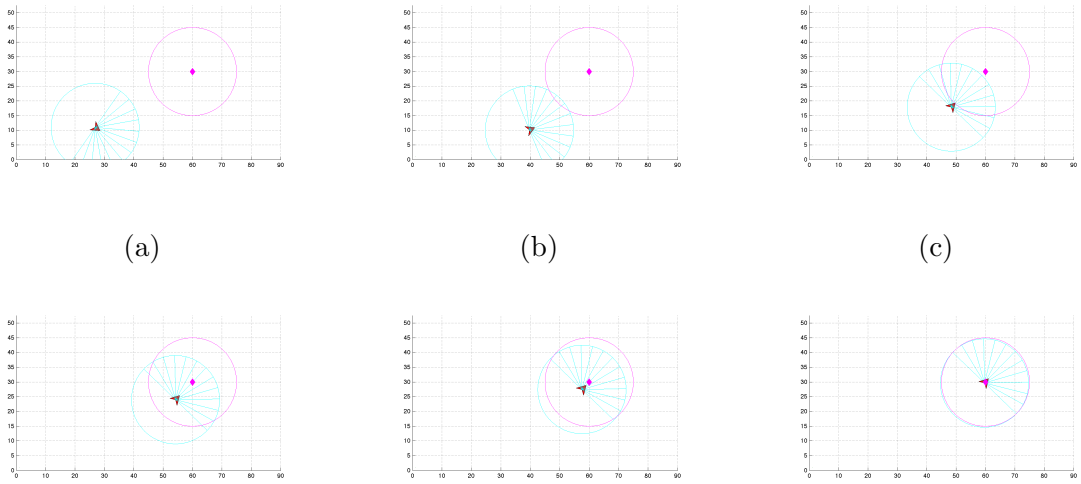
8.3 Simulation Results

8.3.1 Single Robot - No Obstacles

For the single robot simulations, we first wanted to test how the robot was able to navigated through a terrain with no obstacles. Figure 8.4 shows snapshots of the robot as it travels to the goal. The robot was initially placed at an angle of -45 degrees, and using the attractive velocity potential only, it took the shortest and most direct route towards the goal position. As the robot approached the goal and entered the region of interest around the goal (the magenta circle), the robot slowed down until it came to a halt at the goal position.

Figure 8.4 shows snapshots of the simulation animation, and the movement of the robot between the initial and goal position. The simulation successfully proved that the velocity potential approach could be used to navigate a robot to a goal position with no obstacles in the terrain.



(a) (b) (c)

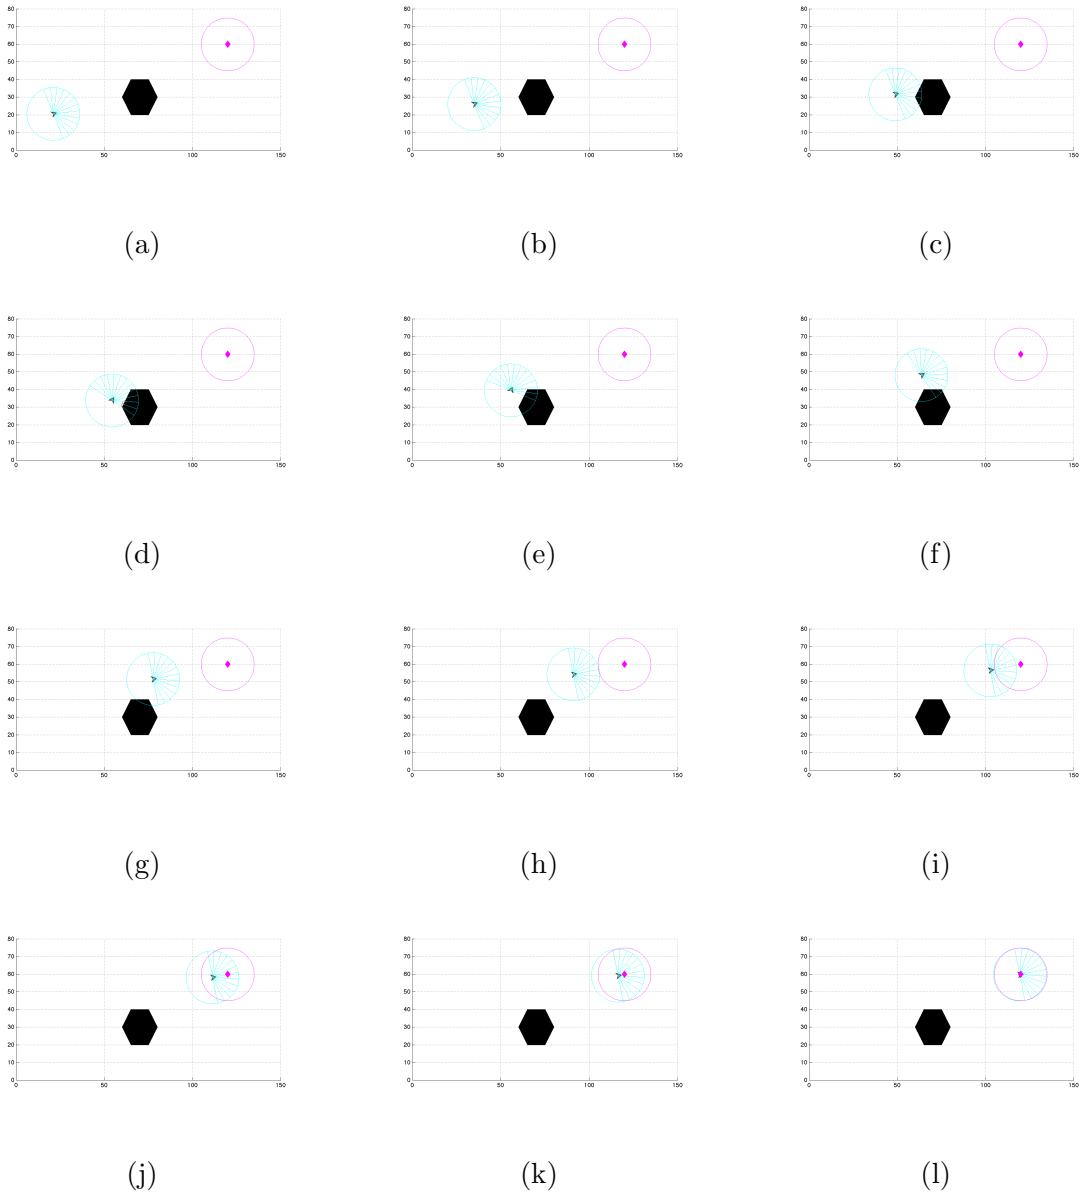
(d) (e) (f)

Figure 8.4: Simulation: no obstacles

8.3.2 Single Robot - With Obstacles

The next simulation placed the robot in a terrain with a simple obstacle. The obstacle was plotted with a hexagon shape, and was placed in the direct path between the robot's initial pose and the goal position. When the robot's sensors sensed the obstacle in the terrain, the shortest sensor range was found and a red circle was plotted at the interface between the shortest sensor beam and the obstacle. The robot then applied the range and angle measurement into its velocity calculation function to navigate the robot around the obstacle and back into the path towards the goal position. Finally, as the robot entered the region of interest around the goal, the robot slowed down and stopped at the goal position. Figure 8.5 displays

snapshots of the simulation for a single robot navigating around an obstacle.



(a) (b) (c)

(d) (e) (f)

(g) (h) (i)

(j) (k) (l)

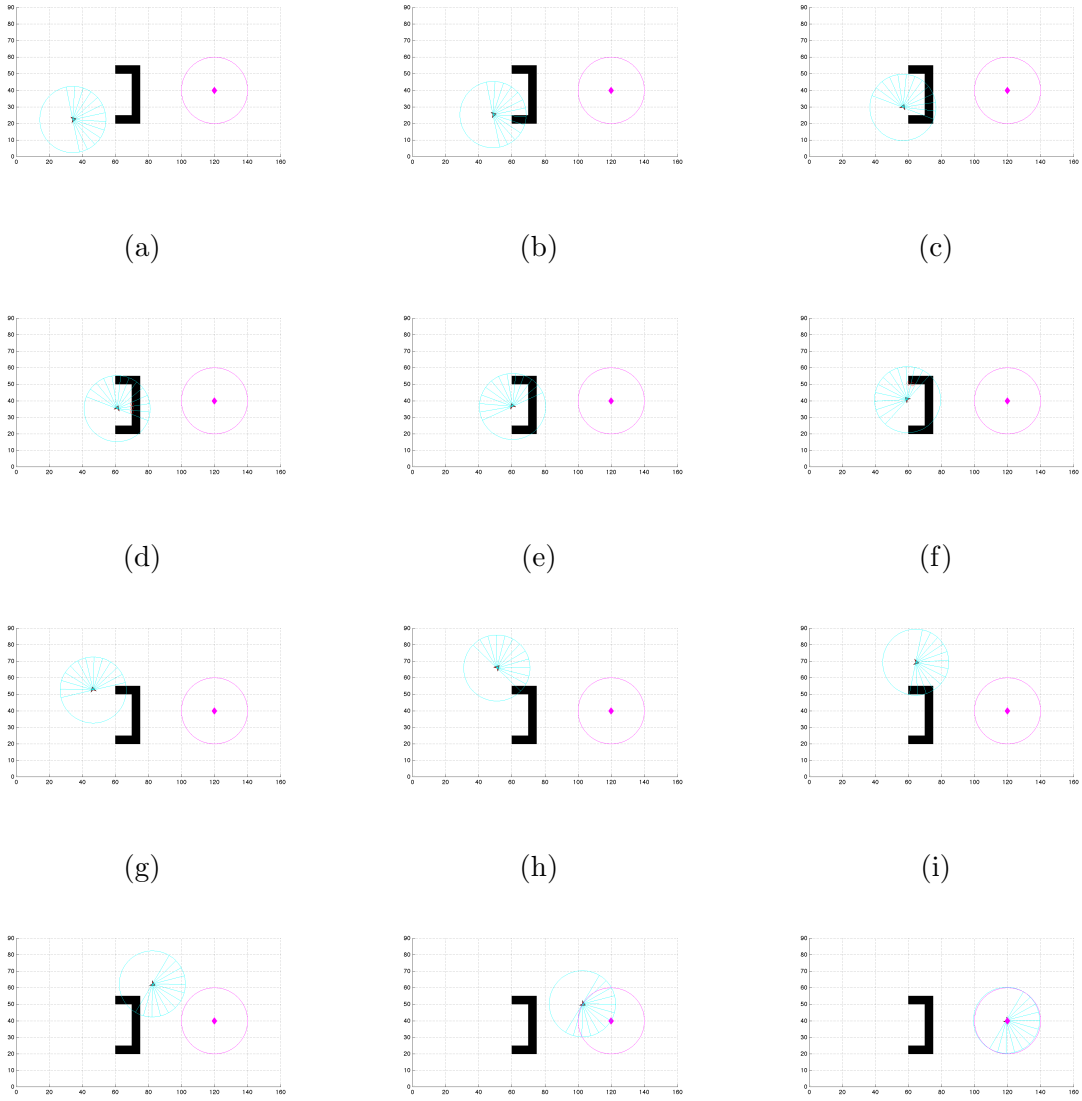
Figure 8.5: Robot travelling around an obstacle

8.3.3 Single Robot Travelling Around a Concave Obstacle

In Chapter 3 and Chapter 4, the Artificial Potential Field (APF) method was discussed. The APF method is a popular reactive navigation controller in mobile robotics, however the algorithm suffers from a local minima problem, which often limits the robot's mobility. The local minima problem causes the robot gets trapped around certain obstacles, and the robot cannot reach its final goal position. Many additions the the APF approach were introduced to address the local minima problem including the addition of Harmonic Potential Fields[20]. The next set of simulations looked to see if our Velocity Potential (VP) method could tackle obstacle shapes that are difficult for the APF method. Two obstacle geometries were considered: (1) the concave obstacle and (2) the narrow passage.

Firstly, the concave obstacle is a very difficult obstacle for the APF method since, when the robot enters the concave obstacle, the robot's attractive and repulsive vectors have equal and opposite magnitudes. This yields a net zero force and stops the vehicle inside the concave obstacle. In order to tackle the concave obstacle with the APF method, additional controllers are required to push the robot away from the concave obstacle.

In our simulations, we wanted to test how the robot behaved when approaching a concave obstacle using the Velocity Potential fluid flow method. The concave obstacle was plotted as a C-shaped polygon in MATLAB, and was placed in the direct path between the robot's initial pose and the goal position. In the simulation, the robot approached the concave obstacle, and then using its normal and tangential velocities, it was able to go around the obstacle until it had a free path towards the goal position. The robot then followed a uniform attractive flow field towards the goal and stopped at the goal position. Figure 8.6 displays the movement of the robot around a concave obstacle, and proves the versatility of the Velocity Potential method when confronting difficult obstacle geometries.



(a) (b) (c)

(d) (e) (f)

(g) (h) (i)

(j) (k) (l)

Figure 8.6: Robot travelling around a concave obstacle

8.3.4 Single Robot Travelling Through a Narrow Passage

Finally, the Velocity Potential method was tested in a narrow passage obstacle. The narrow passage is a difficult obstacle for the APF navigation controller, since it generates a local minimum. For our simulations, the narrow passage was plotted in MATLAB with two trapezoid shapes. Trapezoid shapes were used instead of

rectangle shapes to guide the robots into the narrow opening. In our simulations, the robot was able to successfully navigate through the narrow passage to reach the goal position.

(d) (e) (f)

(g) (h) (i)

(j) (k) (l)

Figure 8.7: Robot travelling through a narrow passage

8.4 Experimental Algorithm

Single robot experiments using the Velocity Potential navigation controller were implemented on the X80 mobile robot. The controller was programmed in C++ using the methods described in Chapter 7. Figure 8.8 shows the main function methodology in the C++ code. The main function was responsible for initializing parameters such as the maximum velocity and angular velocity, the region of interest around the obstacle and goal radius, and constants for control. Furthermore Player Proxies were set in the main function that connected the Personal Computer (PC) to the robot through the wireless network. Finally, the majority of the calculations for robot navigation were carried out in a loop that calculated the velocity based on the Velocity Potential calculations from Chapter 4. The loop continued until the robot reached the goal position, then all robot velocity commands were set to zero, and the experiment was closed.

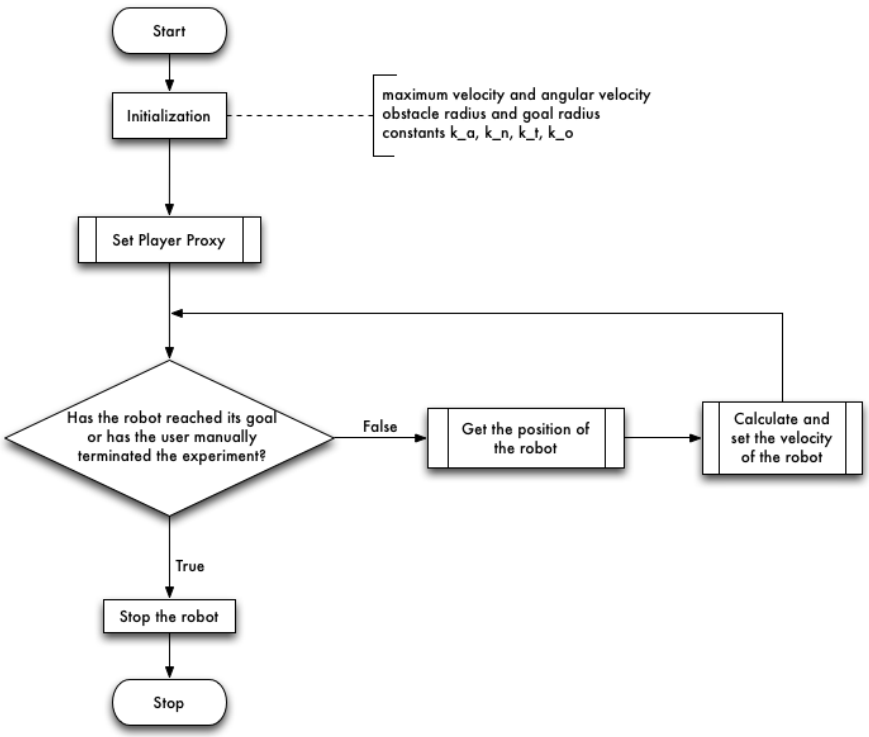

Figure 8.8: main function

The inner workings of the main function are displayed in figures 8.9a, 8.9b, and 8.9c. Firstly, figure 8.9a displays the steps to set the Player Proxy for the client robots. Furthermore, figure 8.9b shows how the controller can access the (x, y, θ) position variables using the GetXPos(), GetYPos, and GetYaw() methods from the Position2dProxy.

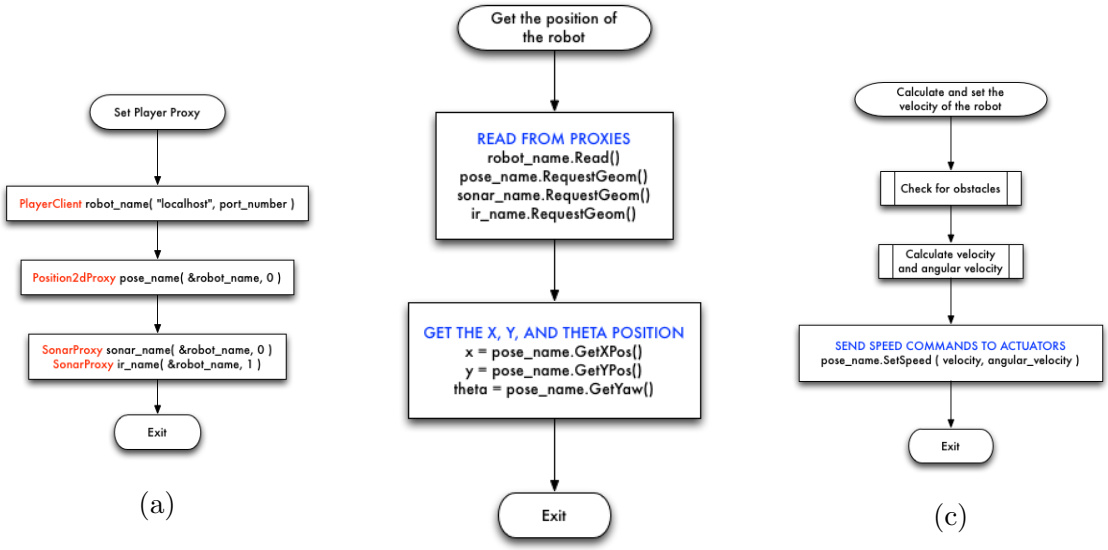

Figure 8.9: (left) set player proxy, (middle) get the robot pose, (right) calculate teh robot velocity

Finally, figure 8.9c displays the steps needed to calculate the velocity of the robot. The robot first checks for obstacles within its viewing range. Figure 8.10a details the steps in the *Check for obstacles* predefined process. After checking for obstacles, the robot calculates its velocity based on the Velocity Potential method from Chapter 4. The details of the implementation of this method in C++ are shown in figure 8.10b. Finally, the robots uses its SetSpeed() method to set the new velocity and angular velocity values onto the X80 robot.

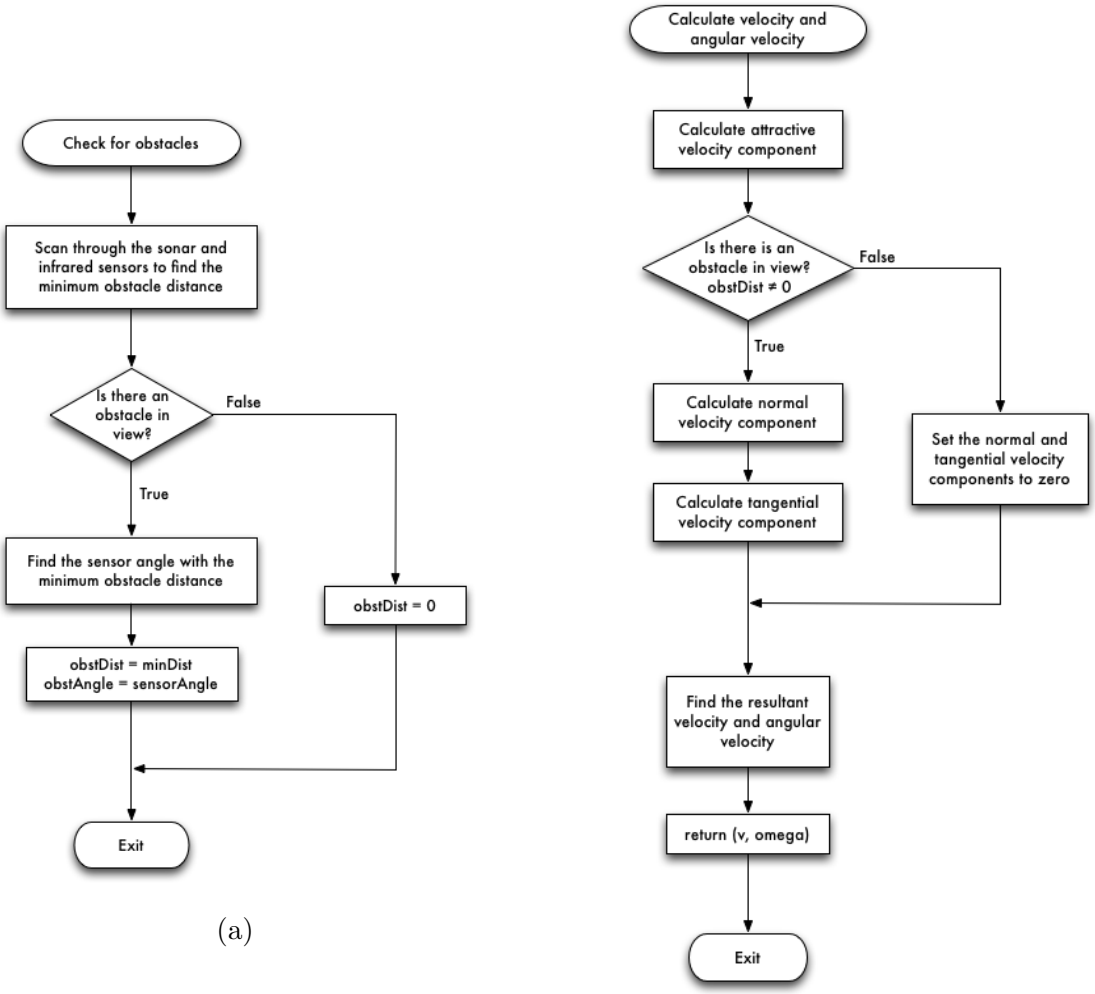

Figure 8.10: (left) check for obstacles, (right) calculate velocity and angular velocity

8.5 Experimental Results

8.5.1 Single Robot Travelling Through a Terrain with Obstacles

Three navigation experiments were tested on the X80 robot using the Velocity Potential navigation controller. The first experiments examined how the X80 mobile robot was able to navigate around simple obstacles in the terrain. In this experiment, potted plants were used as obstacles, and the plants were placed in the direct path between the robot's initial position and the goal position.

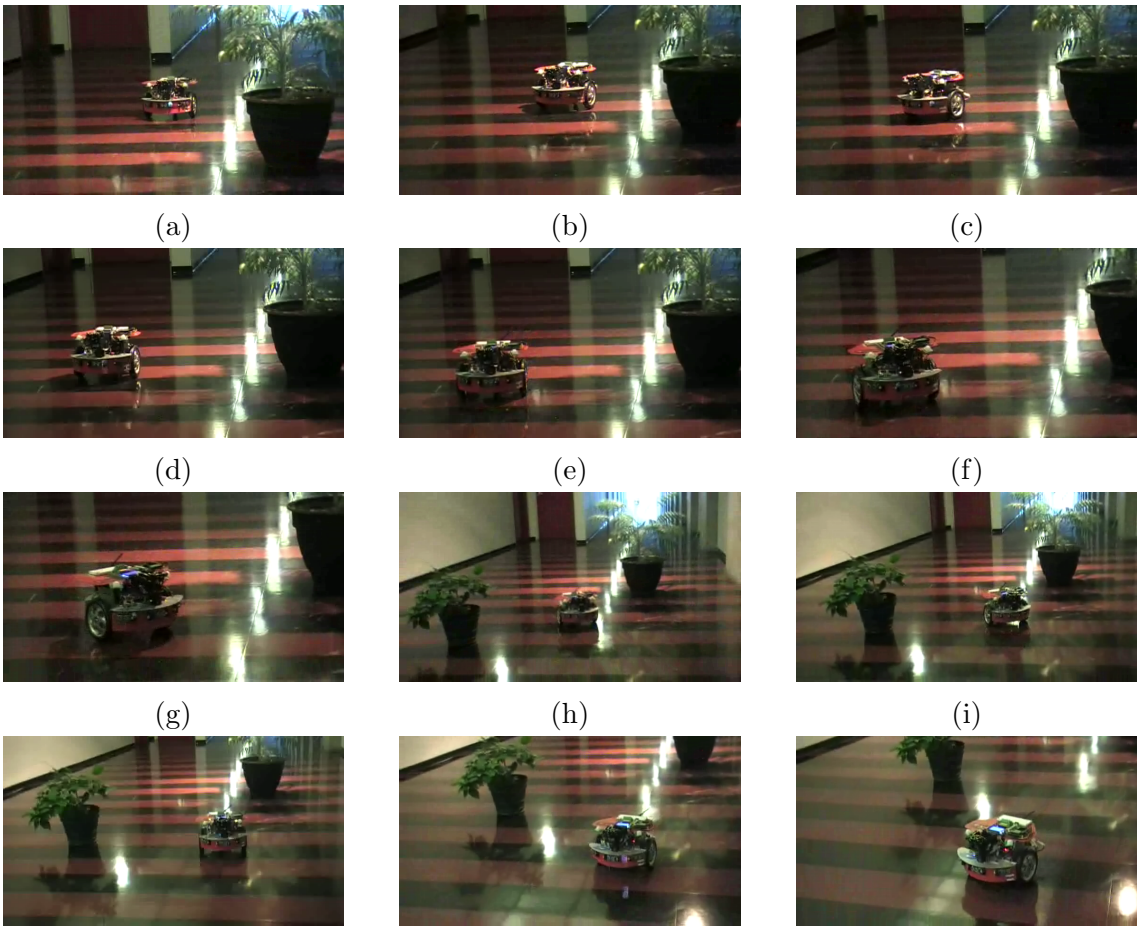

Figure 8.11: X80 navigating aroud an obstacle

Figure 8.11 shows snapshots, at different time intervals, of the robot navigating

around the plants. The robot was able to successfully navigate around the two obstacles and reach the goal position in front of the camera.

8.5.2 Single Robot Travelling Around a Concave Obstacle

In the second experiment, the X80 robot faced the concave obstacle that was built using three boxes. The boxes were paced in a C-shape, and various configurations on the shape of the concave were tested with the X80 robot.

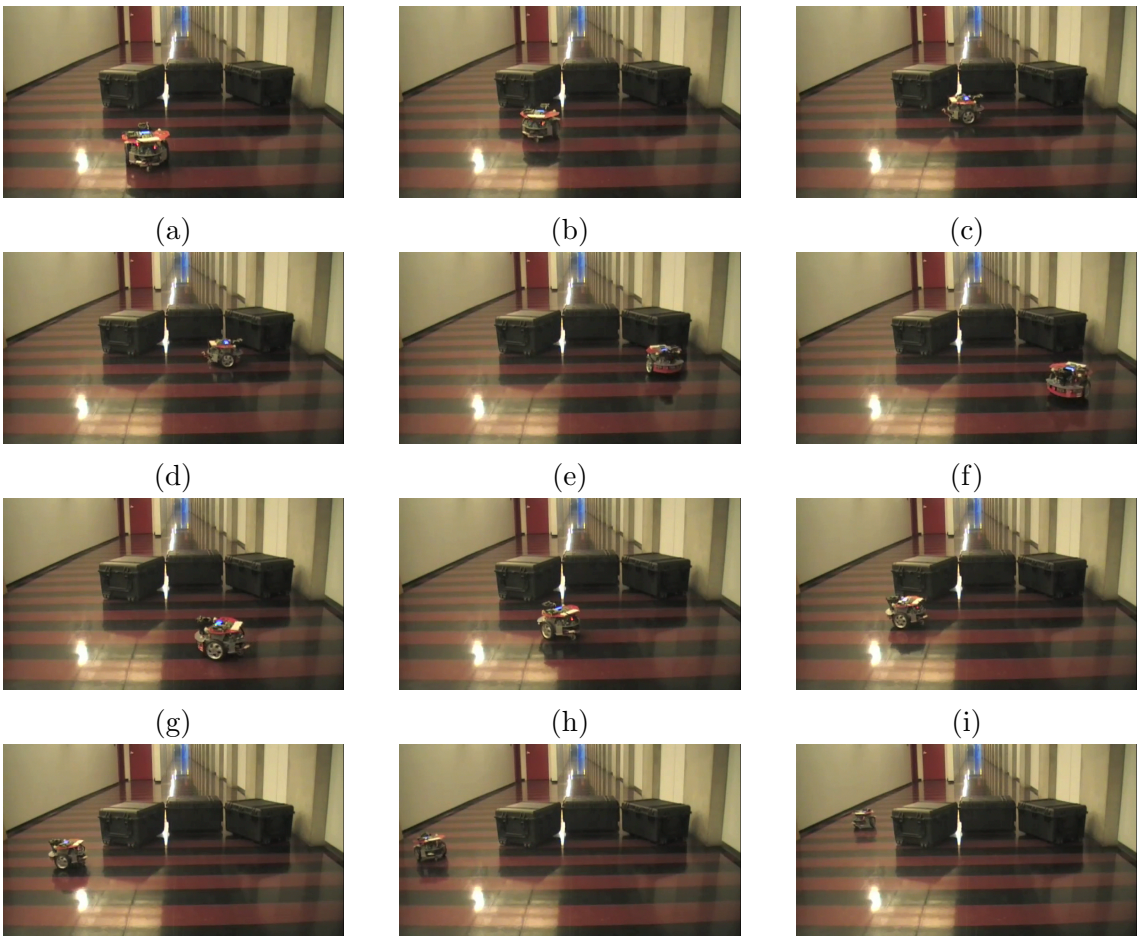

Figure 8.12: X80 travelling around a concave obstacle

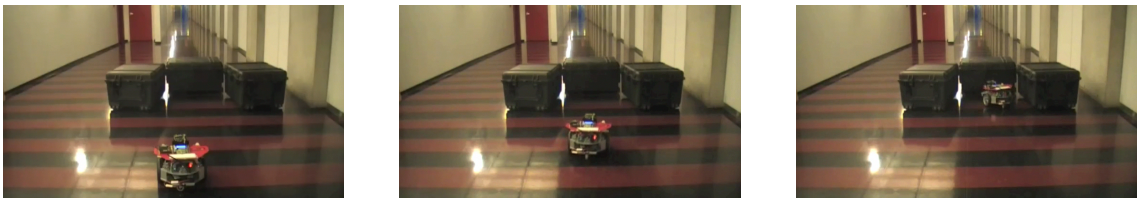
It was found that for most shapes, the robot was able to successfully navigate around the concave obstacle to reach the goal position behind the obstacle. The only case when the robot became stuck was when the C-shape was too narrow, figure 8.13

where the robot had no space to turn around. This was an extreme case for the concave obstacle. All-in-all, the experiments proved that the X80 could successfully navigate around a concave obstacle with the Velocity Potential navigation controller.



(a) (b) (c)

Figure 8.13: Concave obstacle geometry too small for the robot to escape

8.5.3 Single Robot Travelling Through a Narrow Passage

Finally, the last experiment tested how the X80 handled the narrow passage obstacle. A narrow passage was constructed using boxes, and various passage widths were tested. Figure 8.14 shows snapshots of the X80 travelling through the narrow passage to the goal position in front of the camera.

Chapter 9

Results for Geometric Formations

This chapter will look at geometric formation control using the Leader-Follower formation control algorithm developed in Chapter 4. The chapter is organized in two parts: section 9.1 discusses the simulation and experimental results for the leader follower formation travelling through a terrain with no obstacles, and then section 9.2 will discuss the simulation and experimental results for reconfiguring geometric formations navigating through a terrain with obstacles. In this case, the leader navigates to the goal using the Velocity Potential navigation algorithm as seen in Chapter 8, and the followers will organize themselves in a specified geometric shape behind the leader.

9.1 Leader-Follower Formations

9.1.1 Simulation Algorithm

Simulations for the Leader-Follower geometric formation were first carried out in MATLAB using the methodology described in Chapter 7. In this simulation, two robots are plotted in the MATLAB figure window, a red leader robot and a blue follower robot. The leader is given a prescribed trajectory, and the follower tracks the leader a specified distance and angle to follow the leader.

The main function of the LF simulation is shown in figure 9.1a. In the main function constants like the maximum linear and angular velocity, sensor and goal region of interest, controller constants, and map dimensions are set. Further the user can input robot variables such as the leader initial pose and velocity profile, the follower initial pose, and the desired distance and angle for the follower behind the leader. The main calculations occur in a loop that continues until the simulation time runs out.

The calculations in the loop are shown in figure 9.1b. The simulation first converts cartesian coordinates into polar coordinates. The leader position is then calculated based on the prescribed velocity inputs. Once the leader position is known, the follower calculates its velocity parameters based on the equations from Chapter 4. Polar coordinates are obtained using the ordinary differential equation function in polar coordinates, and then coordinates are converted back into cartesian coordinates. The leader and follower positions are plotted in the MATLAB figure window.

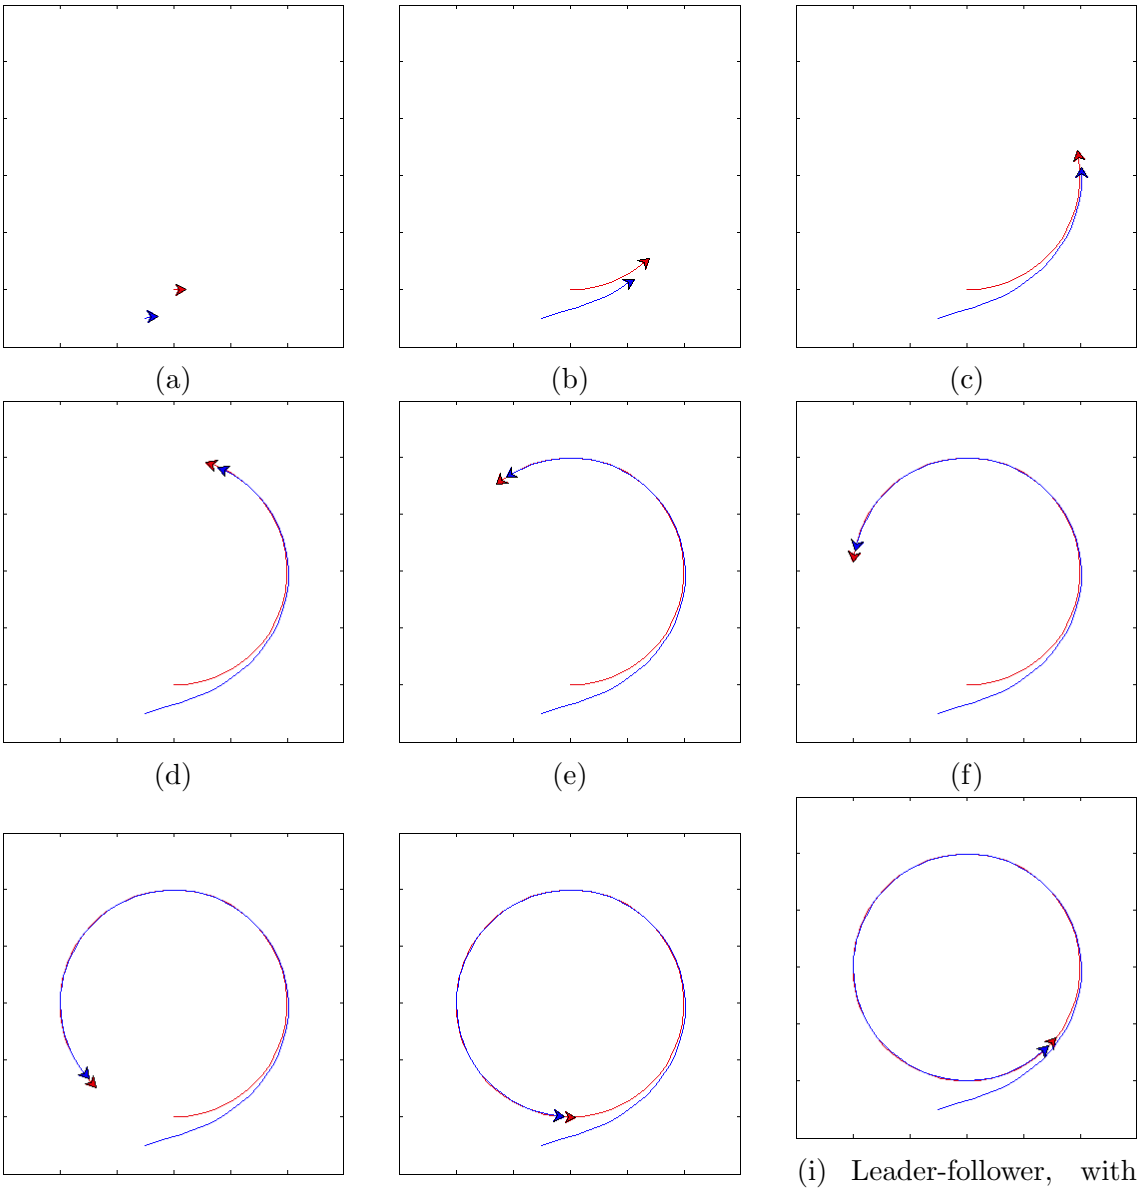
Figure 9.1: (left) main function, (right) robot calculations

9.1.2 Simulation Results

9.1.2.1 Leader-Follower - 0 Degrees

The kinematic model and controller equations for the Leader-Follower setup were programmed in MATLAB to assess their validity. In the simulation we have two robots, one Leader (red) and a Follower (blue) at a random distance behind the Leader. In the first case, we set the Leader and Follower to be initially oriented in the same direction ($\theta = 0$). We set the desired distance between the Leader and Follower to be 1 m, and the angle to be zero so that the Follower would lie directly behind the Leader. Once the Leader vehicle began to move, the Follower adjusted its velocity and angular velocity to catch up with the Leader, and in figure 9.2 we saw that the two robots were moving in-sync with the Follower at a constant distance behind the Leader.



(a) (b) (c) (d) (e) (f) (g) (h)

(i) Leader-follower, with leader at a 0 degree angle with the leader

Figure 9.2: Leader-follower, with the follower at a 0 degree angle from the leader

9.1.2.2 Leader-Follower - 180 Degrees

Several other initial orientations were tested to see if the Leader-Follower model was a success. The most interesting results occurred when the Follower vehicle was initially pointing in the opposite direction of the Leader vehicle. The results pointed out the validity of Brocketts theorem[6], nonholonomic systems cannot be

asymptotically stabilized around a fixed point under any smooth time-independent state feedback control law. A continuous solution for asymptotic stability does not exist for nonholonomic vehicles, and instead, discontinuous or time-varying inputs should be applied.

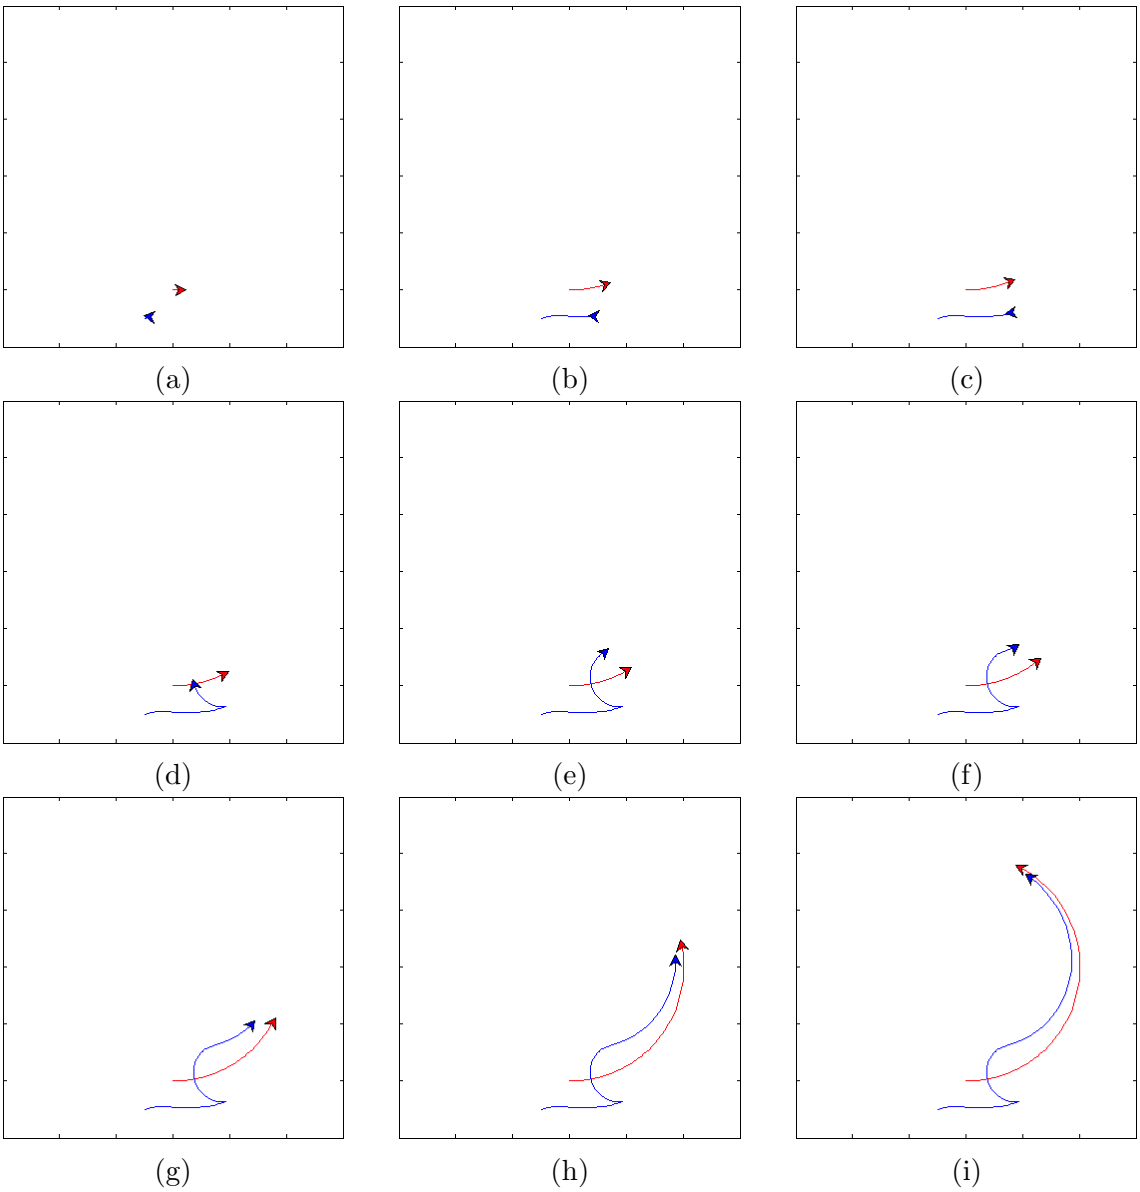


Figure 9.3: Leader-follower, with the follower at a 180 degree angle from the leader

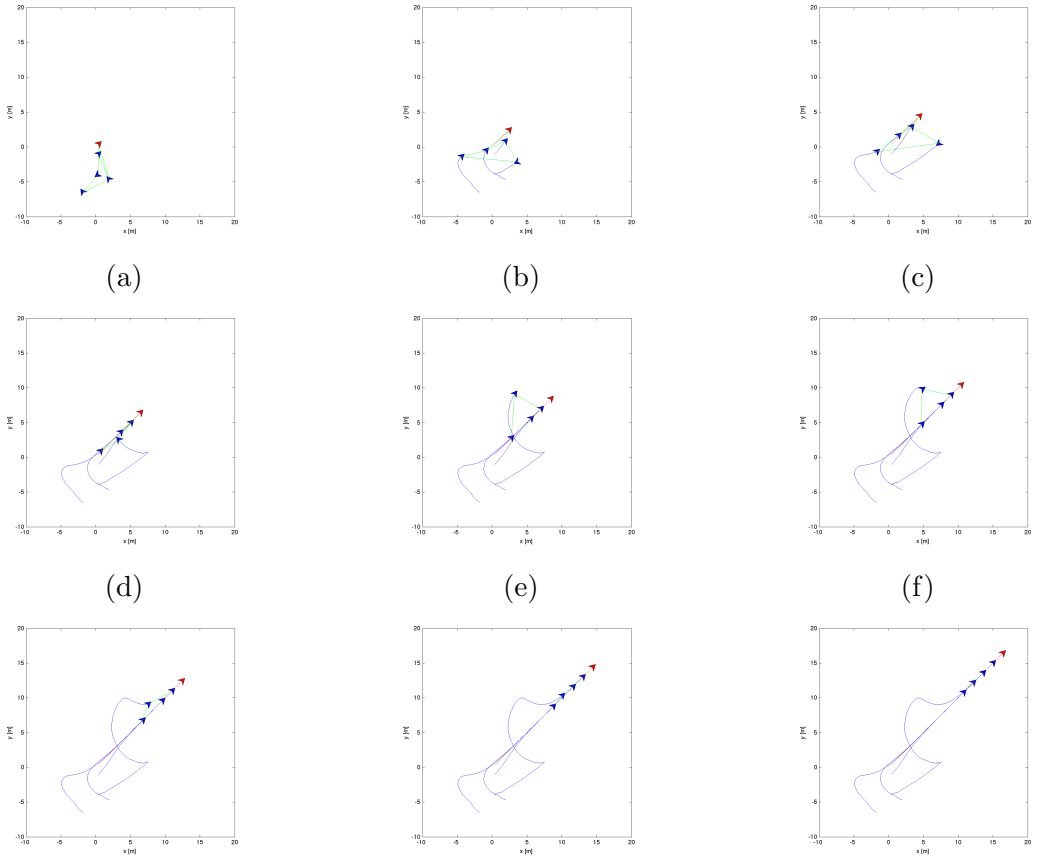
In our simulations, when the Follower vehicle was positioned in the opposite direction to the Leader vehicle, the Follower would need to take a series of discontinuous movements in order to approach the Leading vehicle. For the case when the

Follower was positioned at 135 degrees from the Leader, the Follower was required to stop and let the Leader go ahead before the Follower began moving again behind the Leader. In the case where the Follower was positioned at 180 degrees from the Leader, the Follower initially moved backwards, stopped, then turned and moved in a forward direction to steer itself behind the Leader. Figure 9.3 shows the movement of the follower robot when it is initially positioned 180 degrees from the leader robot.

9.1.2.3 Platoon Formation

A platoon is a formation where a group of vehicles lines up one behind the other. It is a very simple and effective formation that is used when a group of vehicles must travel on a road, or through a tight space. The platoon is a direct application of the Leader-Follower formation, with one Leader that can be placed either in the front, middle, or end of the chain, and multiple Followers that follow the Leaders motion. In this simulation five nonholonomic vehicles are used, where four Followers (blue) are randomly placed behind a Leader (red) that moves in a straight line. By implementing the Leader-Follower controller, each Follower vehicle moves in its own specific way behind the Leader with the goal of orienting themselves at their position behind the Leader. The key to achieving this formation is to implement controller variables $rho_{desired} = 1$ m and $alpha_{desired} = 0$. In this simulation, the first, second, and fourth following vehicles were able to steer themselves quite easily behind the Leader due to their initial orientations. However, due to its initial pose, the third vehicle was required to move backwards for a short while, stop, then turn around and move forwards again to pursue the Leader, demonstrating several discontinuous motions.



(a) (b) (c)

(d) (e) (f)

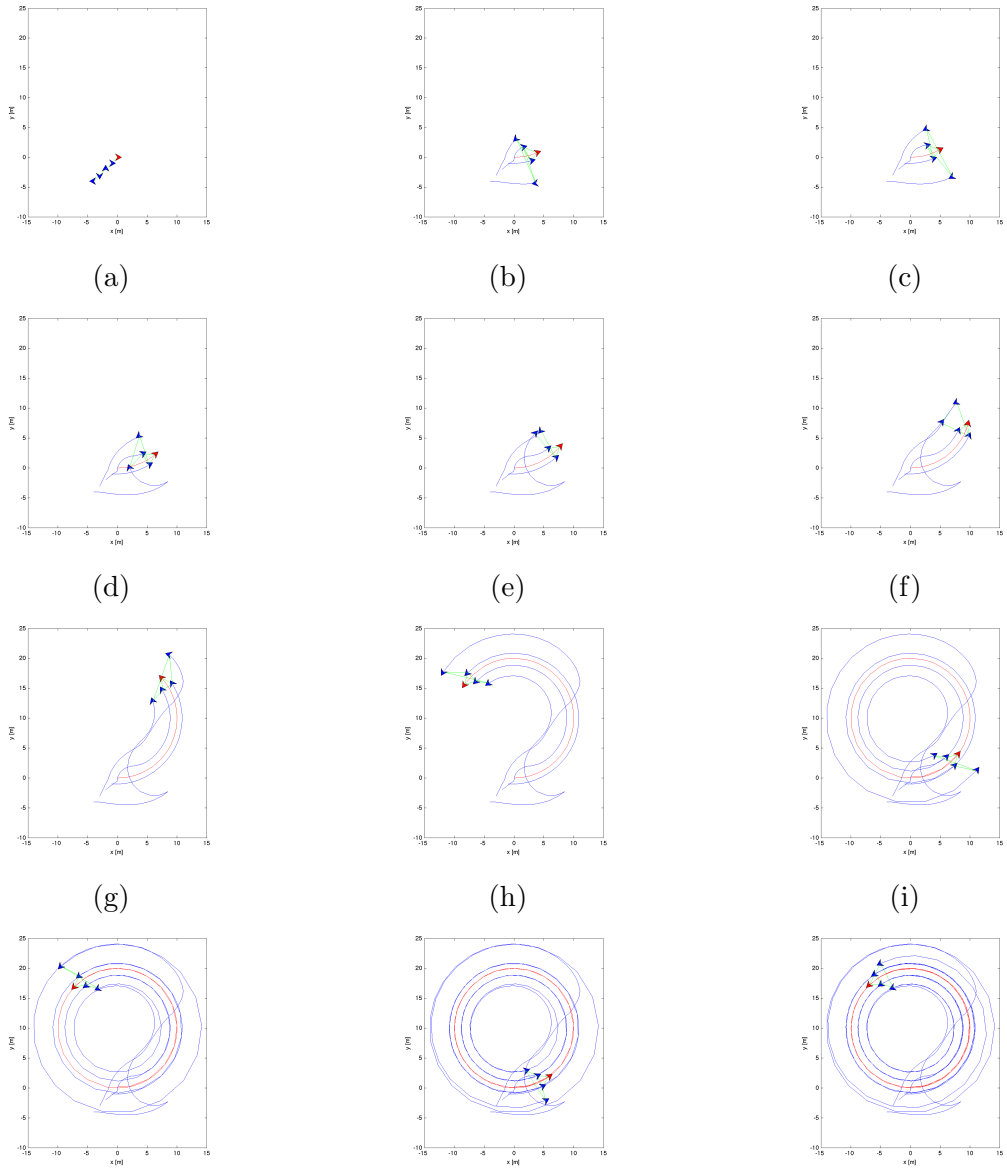
(g) (h) (i)

Figure 9.4: Platoon formation

9.1.2.4 V-Formation

The V-Formation is a geometry taken from nature that resembles Canada Geese flying south. The V-Formation is often used during the transition time, when string of vehicles moving in a platoon wish to spread out into a horizontal line similar to soldiers marching. The formation has one Leader at the front of the pack (red) and four Followers positioned at random behind the Leader. In this simulation, the Leader is moving in a circle at a constant velocity, and the Followers try to orient themselves behind the Leader while creating a V-shape. The key to achieving this formation is to implement the Leader-Follower controller using variables $rho_{desired} = 1$ and $alpha_{desired} = pi/6$ rad. Similar to the platoon, two of the Followers are

able to orient themselves quite easily behind the Leader by moving in a forward direction, while the two other vehicles are required to take a series of discontinuous movements, moving backwards and turning around, before they can get to the right position behind the Leader.



(a) (b) (c)

(d) (e) (f)

(g) (h) (i)

(j) (k) (l)

Figure 9.5: V-formation

9.1.3 Experimental Algorithm

Geometric formation experiments using the Leader-Follower controller were implemented on the X80 mobile robot. In the simulations we used five robots to show the over geometric shape and movement of the robots through the terrain. For experiments we had three differential drive X80 robots, so all experiments consisted of one leader and two follower robots. The formation controller was programmed in C++ using the methods described in Chapter 7. Figure 9.6 shows the main function in the geometric formation controller. The main function initializes parameters and asks the user for inputs such as the goal position and the number of follower robots. The function then calls the Player Proxies to set up the network connection between the robots and Personal Computer (PC). Finally, the majority of the calculations for robot navigation were carried out in a loop that calculated the leader and follower velocities. The loop continued until the robot reached the goal position, then all robot velocity commands were set to zero, and the experiment was closed.

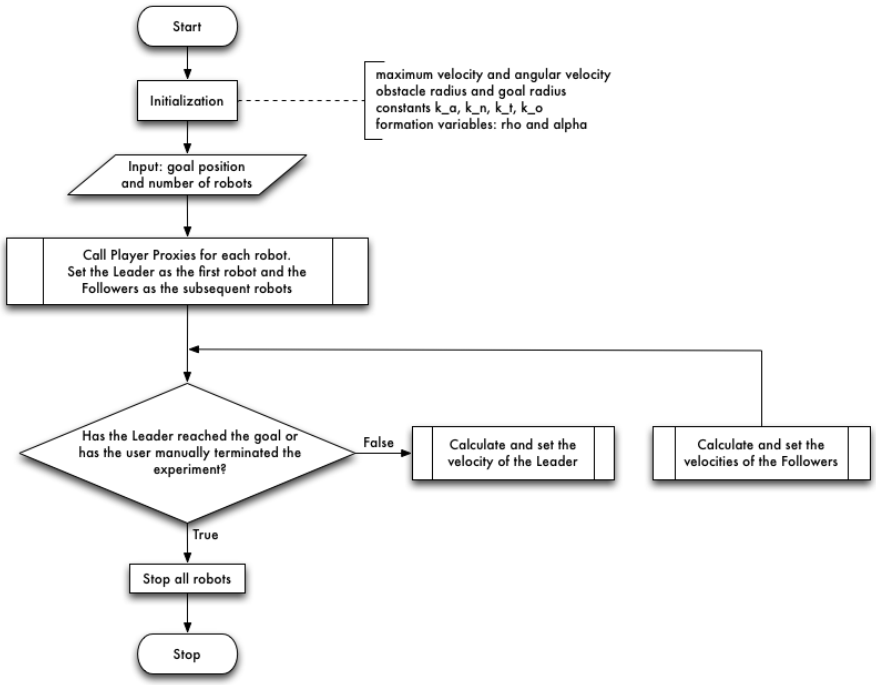


Figure 9.6: main function

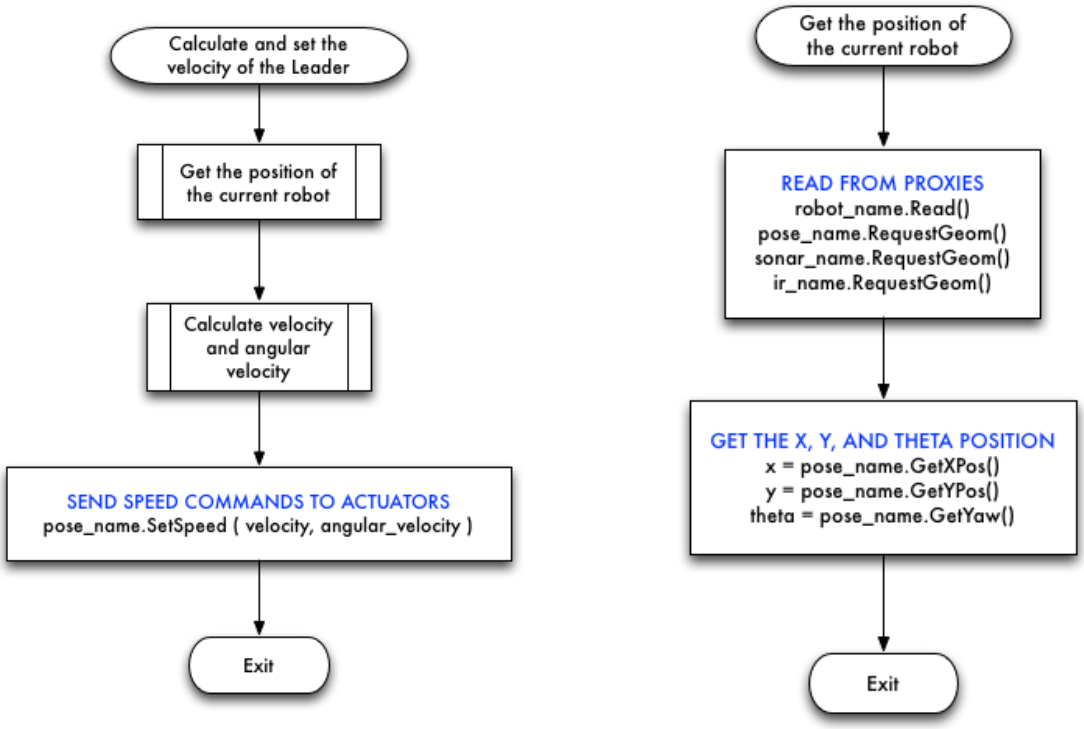

Figure 9.7: (left) calculate leader, (right) get leader pose

In the main loop, the controller calculates and sets the velocity of the leader and follower robots. The steps to carry out these tasks are shown in figure 9.7a and figure 9.9. In figure 9.7a, the leader velocity is calculated by first obstaining the current position of the leader robot. The current position can be found using the methodology of figure 9.7b, where the controller can access the (x, y, θ) position variables using the GetXPos(), GetYPos, and GetYaw() methods from the Position2dProxy. Once the position of the leader robot is found, the controller calculates the velocity and angular velocity based on the algorithm in figure 9.8. The velocity of the follower robots is calculated by first accessing its position variables, and then applying the follower velocity controller from Chapter 4. The leader and follower velocities are then implemented using the SetSpeed() method in the main controller function.

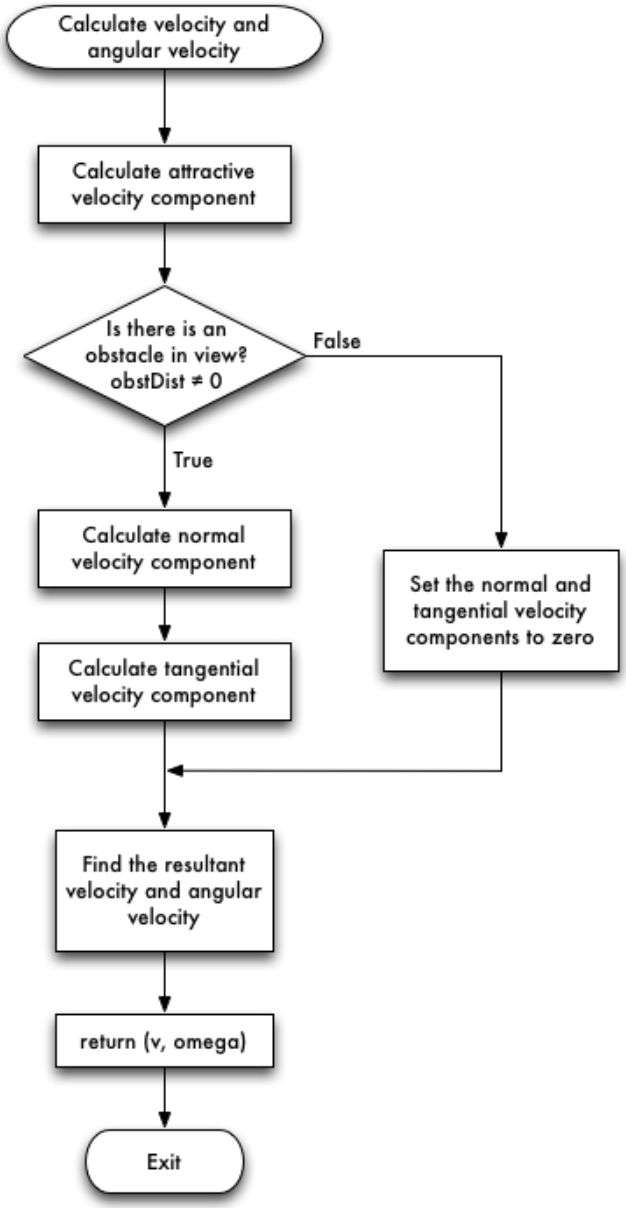

Figure 9.8: Calculate velocity and angular velocity

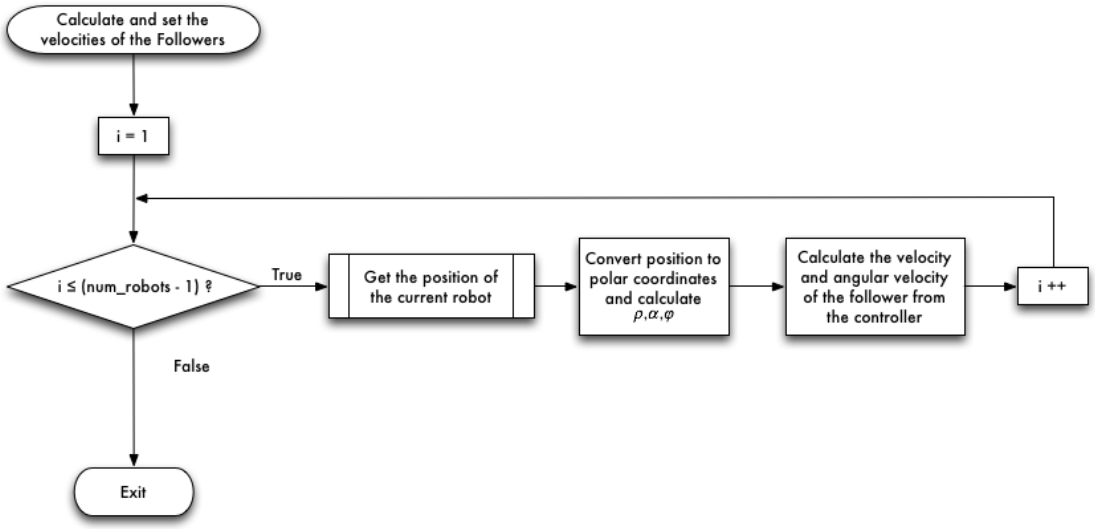

Figure 9.9: Calculate the velocity of the follower

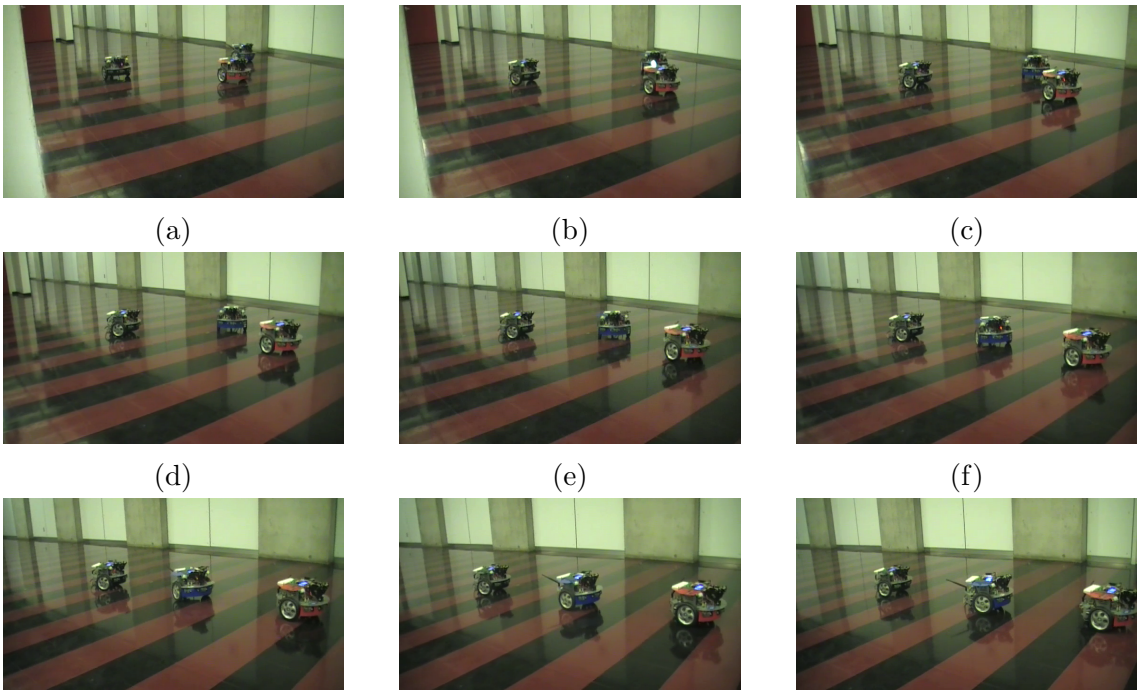
9.1.4 Experimental Results

9.1.4.1 Platoon

In the first geometric formation control experiment with the X80 we wanted to test the platoon formation controller. In this experiment, the robots were initially placed in a V-formation with the red robot in the leader position at the front, and the blue and black follower robots were positioned behind the leader. The leader robot was set to go in a straight path with a constant velocity. When the leader began moving, the blue robot navigated itself behind the red leader. The black robot waited until the blue robot was ahead and then followed the formation behind the blue robot. Figure 9.10 shows the movement of the three robots to position themselves in a straight line platoon formation behind the red leader robot.



(a) (b) (c)

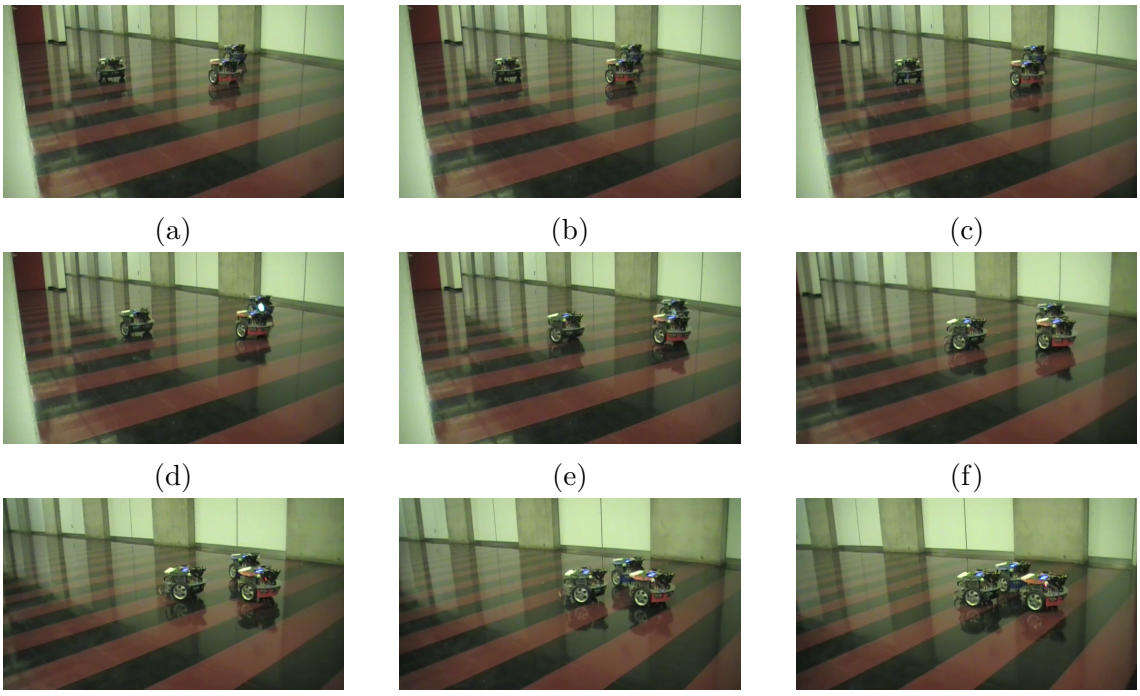
(d) (e) (f)

(g) (h) (i)

Figure 9.10: Platoon

9.1.4.2 V-Formation

In the next experiment, the V-formation was tested with the same initial setup as the Platoon formation. In this experiment, the leader robot travelled on a straight path with a constant velocity. The follower vehicles positioned themselves at a 45 degree angle from the leader position and with a 1 meter distance from the center of gravity of each robot unit. The experiment showed that the V-formation could be achieved with the X80 mobile robots using the Leader-Follower controller.



(a) (b) (c)

(d) (e) (f)

(g) (h) (i)

Figure 9.11: V-formation

9.2 Geometric Formation and Collision Avoidance

9.2.1 Simulation Algorithm

The next stage in the simulations was to incorporate collision avoidance for the group as they travelled together through the terrain. The velocity potential method was used to navigate the leader of the group to the goal while avoiding obstacles. The follower robots tracked the leader at a designated distance and angle, based on the desired formation shape. Figure 9.12 shows a flowchart of the main function of the geometric formation and collision avoidance algorithm.

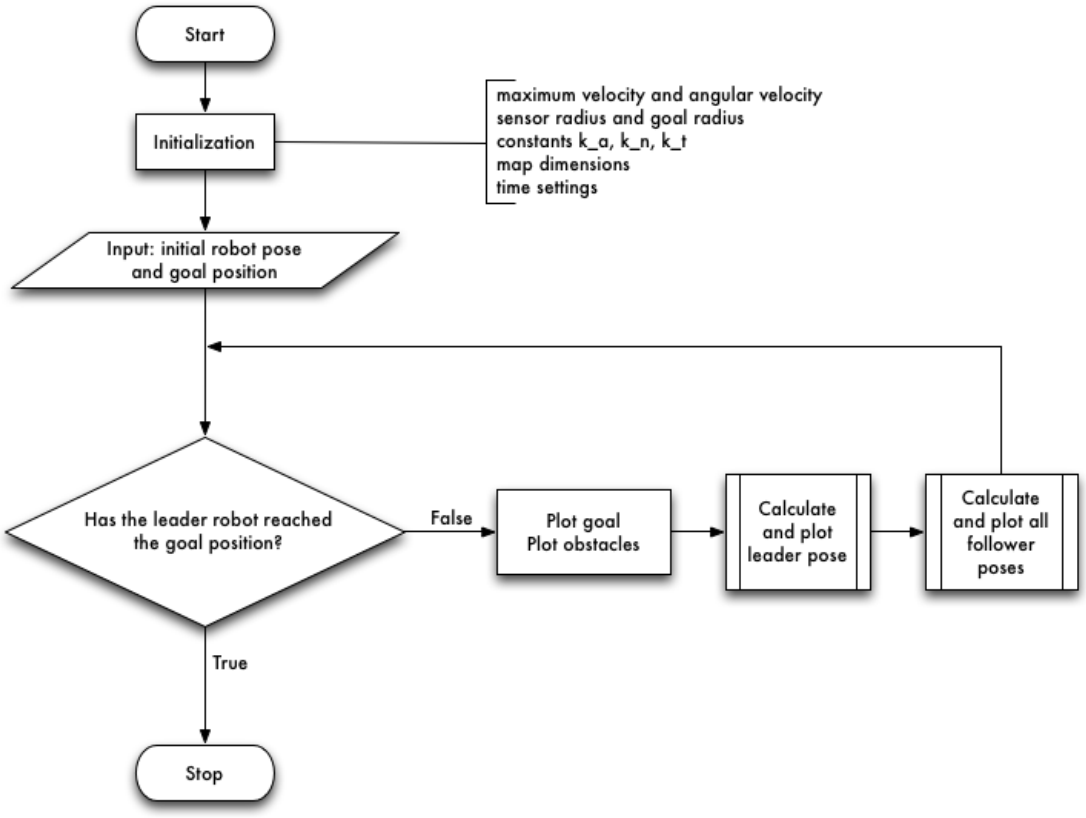


Figure 9.12: main function

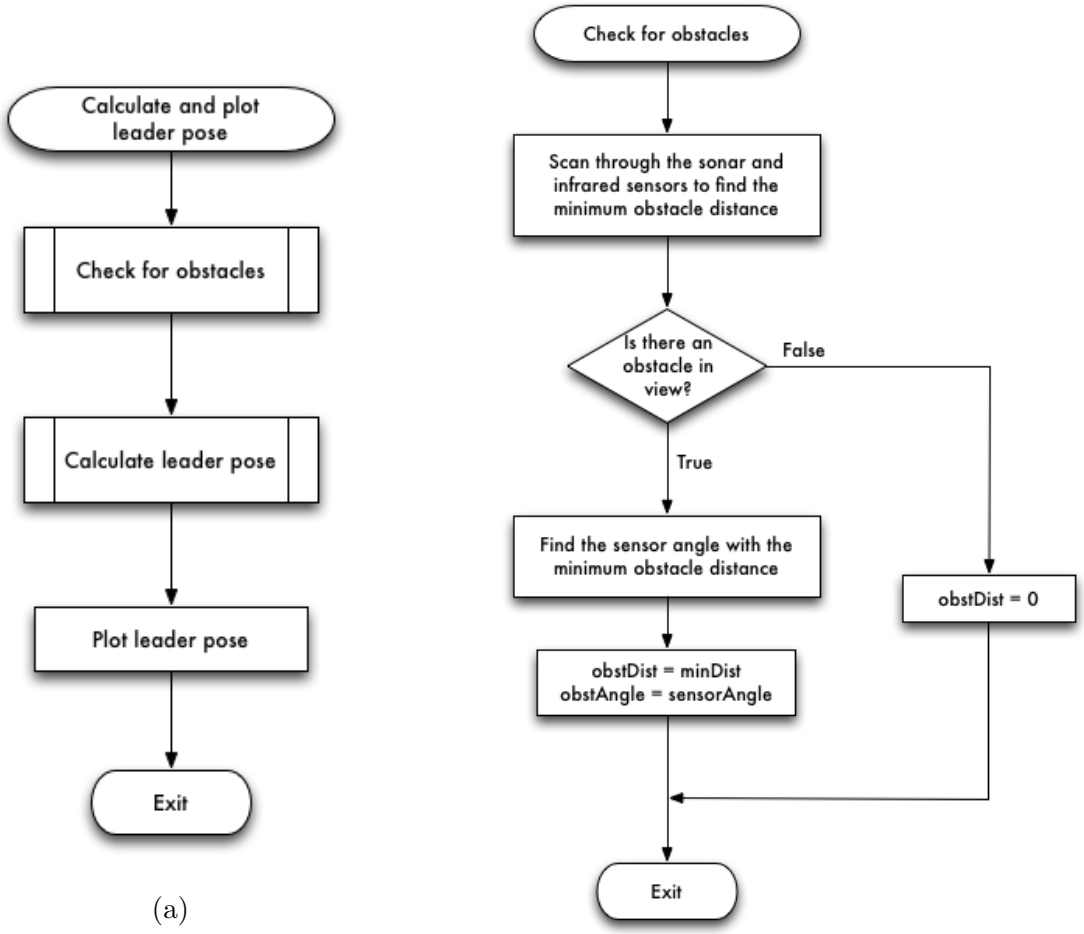
The leader robot implements the reactive navigation strategy of the velocity potential method (figure 9.13a). Firstly the leader checks for obstacles (figure 9.13b) and uses the attractive and repulsive flow fields to determine its next pose (figure 9.14).



(a)

(b)

Figure 9.13: (left) calculate and plot leader pose, (right) check for obstacles

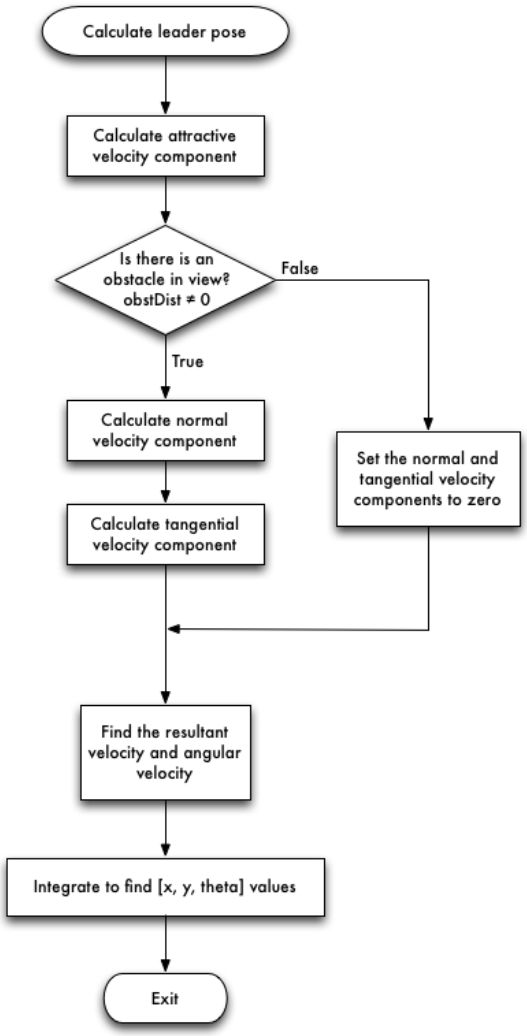


Figure 9.14: Calculate leader pose

Finally, the new follower pose is calculated based on the leader-follower controller shown in figure 9.15

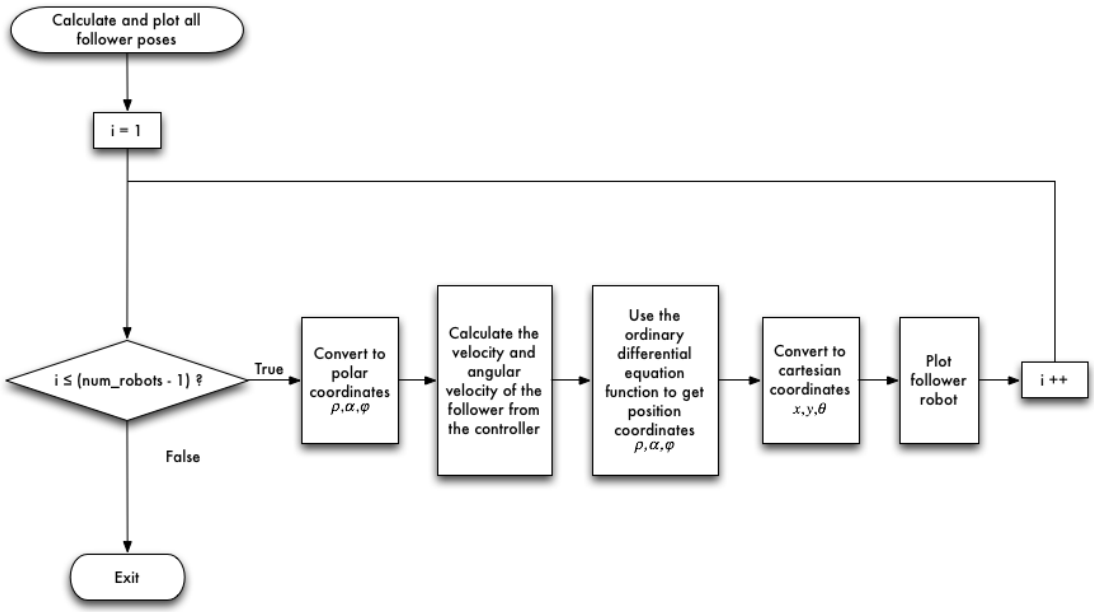

Figure 9.15: calculate follower pose

9.2.2 Simulation Results

9.2.2.1 Platoon

In the first simulation, a leader robot (red) navigates around a hexagon shaped obstacle to reach the goal position. The follower robots (blue) navigate around the obstacle by creating a platoon formation behind the leader. It was found that the platoon formation worked only for small groups of robots, and the longer the platoon chain, the more susceptible the formation was to collisions with obstacles. For a simulation with five robots, the platoon formation was able to successfully navigate around the obstacle and reach the goal position.

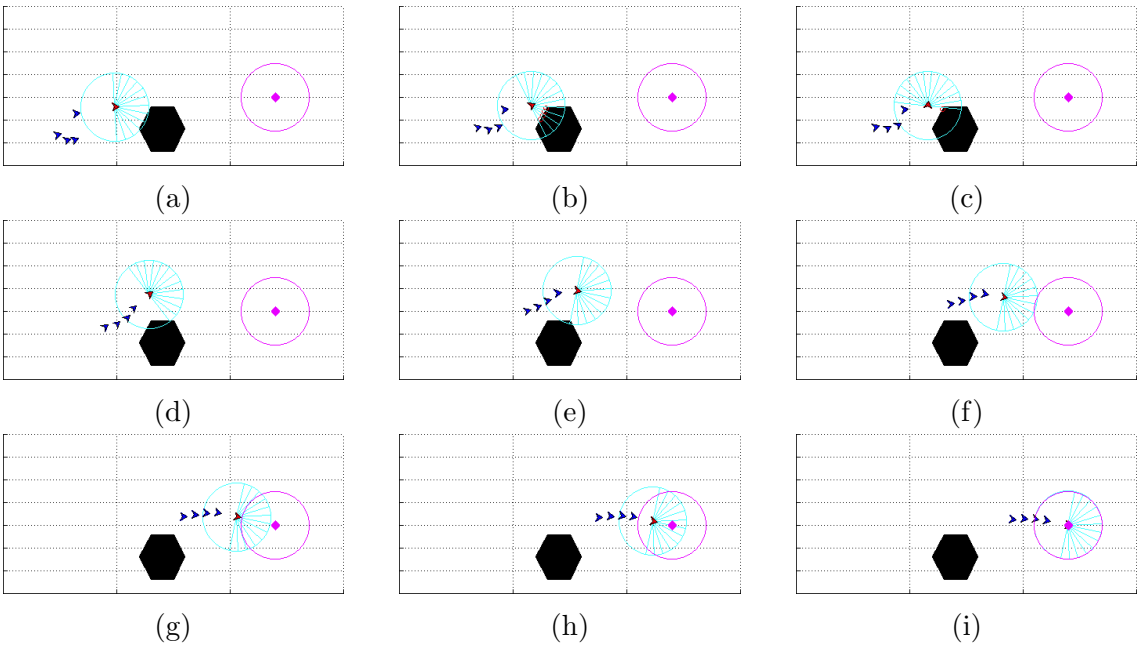

Figure 9.16: Platoon around an obstacle

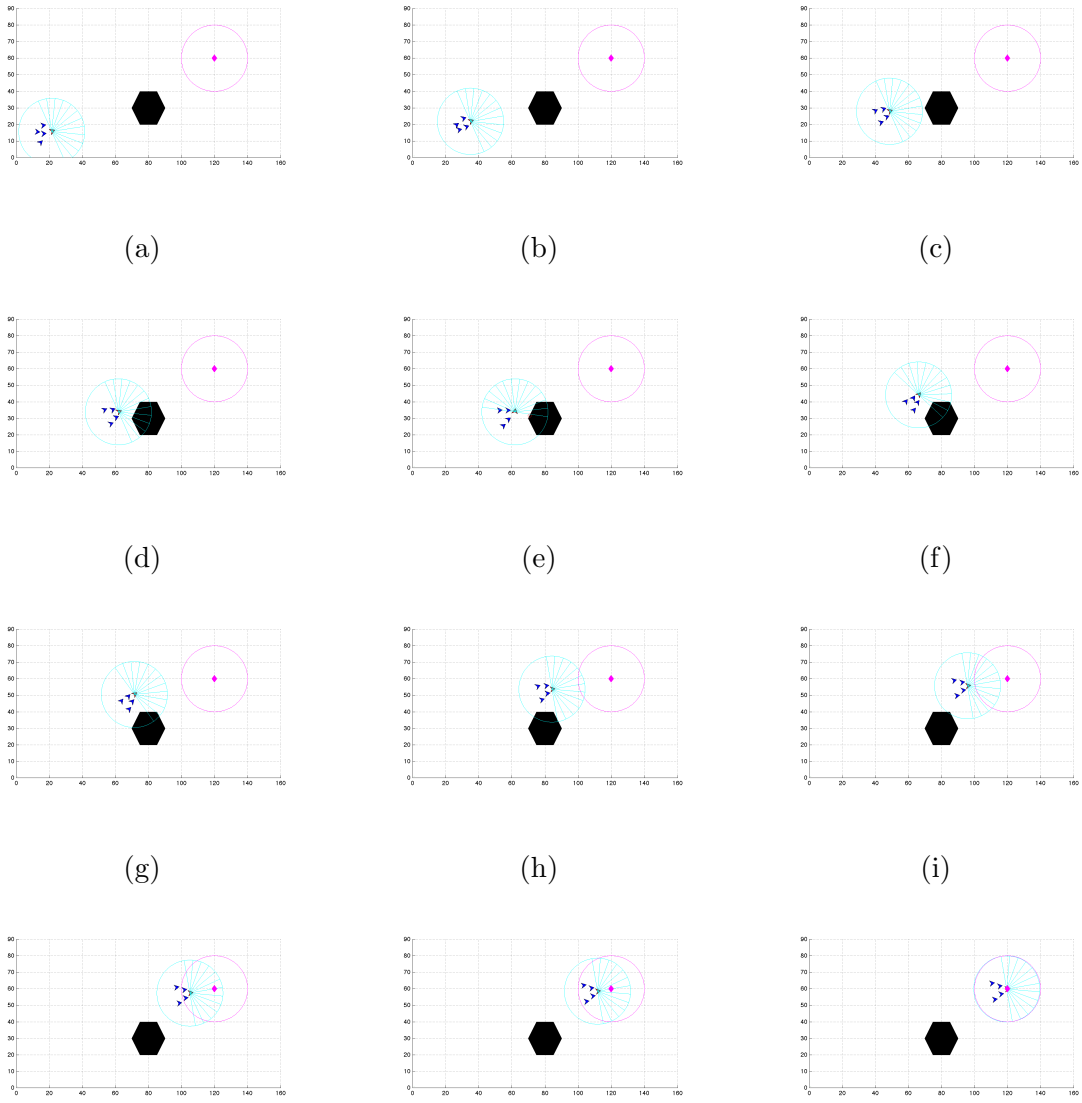
9.2.2.2 V-formation

The next simulation tested how a V-formation could navigate around a hexagon shaped obstacle. Reconfiguring formations was a very important concept when designing the LF formation controller, and when designing the algorithm we set the angle of the V to change when an obstacle is in view. In the simulation, when

the group approached an obstacle, the angle of the formation shrank to more easily accommodate the group and allow them to navigate around the obstacle without collisions. Figure 9.17 shows snapshots of the LF simulation for a V-formation around an obstacle. The simulation successfully demonstrated that a V-formation could easily navigate around the obstacle as a group using the Velocity Potential navigation controller.



(a) (b) (c)

(d) (e) (f)

(g) (h) (i)

(j) (k) (l)

Figure 9.17: V-formation around an obstacle

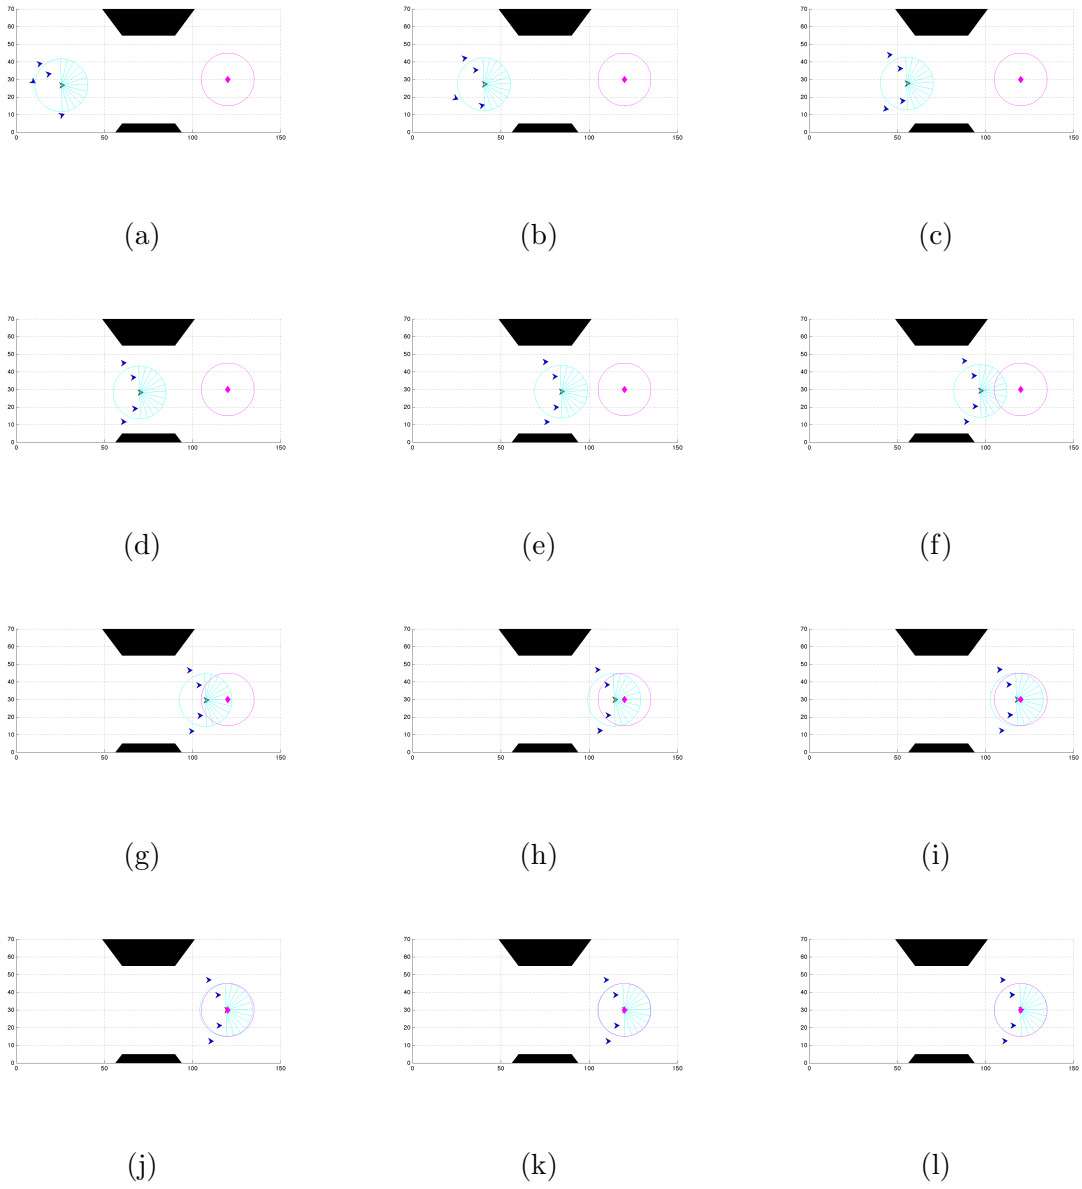
9.2.2.3 V-Formation Around a Concave Obstacle

The third simulation incorporated a concave obstacle for a team of mobile robots. Figure 9.18 shows snapshots of the LF movement around a concave obstacle. In this simulation the leader enters into the concave obstacle, and using the velocity potential navigation controller it finds a way to escape from the obstacle and to travel to the goal position. In the process, the follower robots back up to accommodate the leader, and then orient themselves in a V-formation behind the leader to reach the goal position.

Figure 9.18: V-formation around a concave obstacle

9.2.2.4 V-Formation Through a Wide Passage

In the fourth simulation, a V-formation navigated through a wide passage. The angle of the V-formation was set to change according to the obstacle opening distance, determined by the leader robot. For the wide passage in figure 9.19, the opening was large enough that all of the robots could pass without having to change the angle of the V.



(a) (b) (c)

(d) (e) (f)

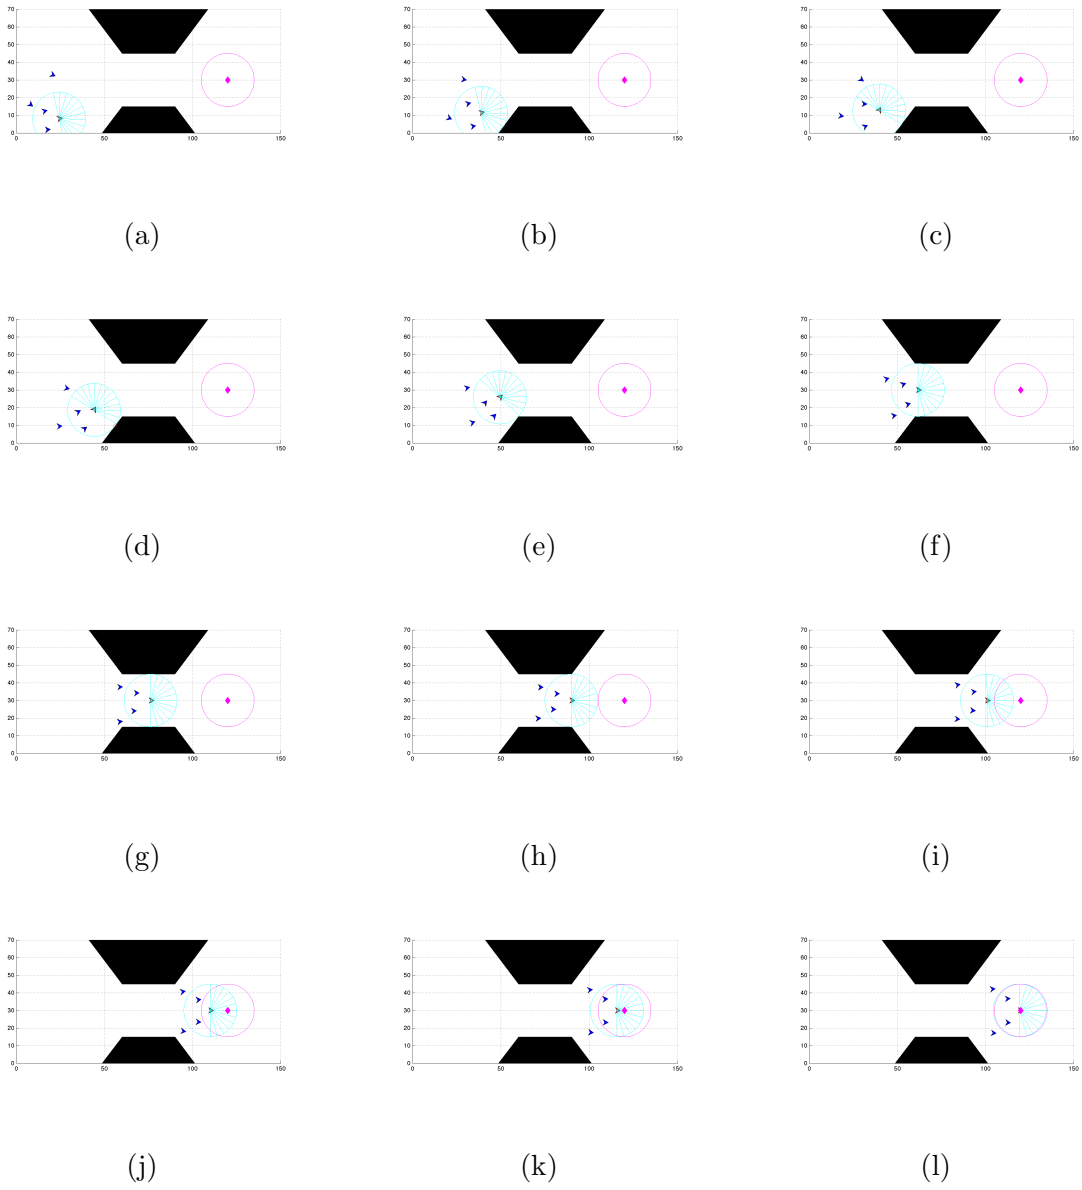
(g) (h) (i)

(j) (k) (l)

Figure 9.19: V-formation through a wide passage

9.2.2.5 V-Formation Through a Narrow Passage

For the fifth simulation, the V-formation was tested with a narrow passage. This narrow passage was small enough that the team of robots could not pass through with their original formation angle.



(a) (b) (c)

(d) (e) (f)

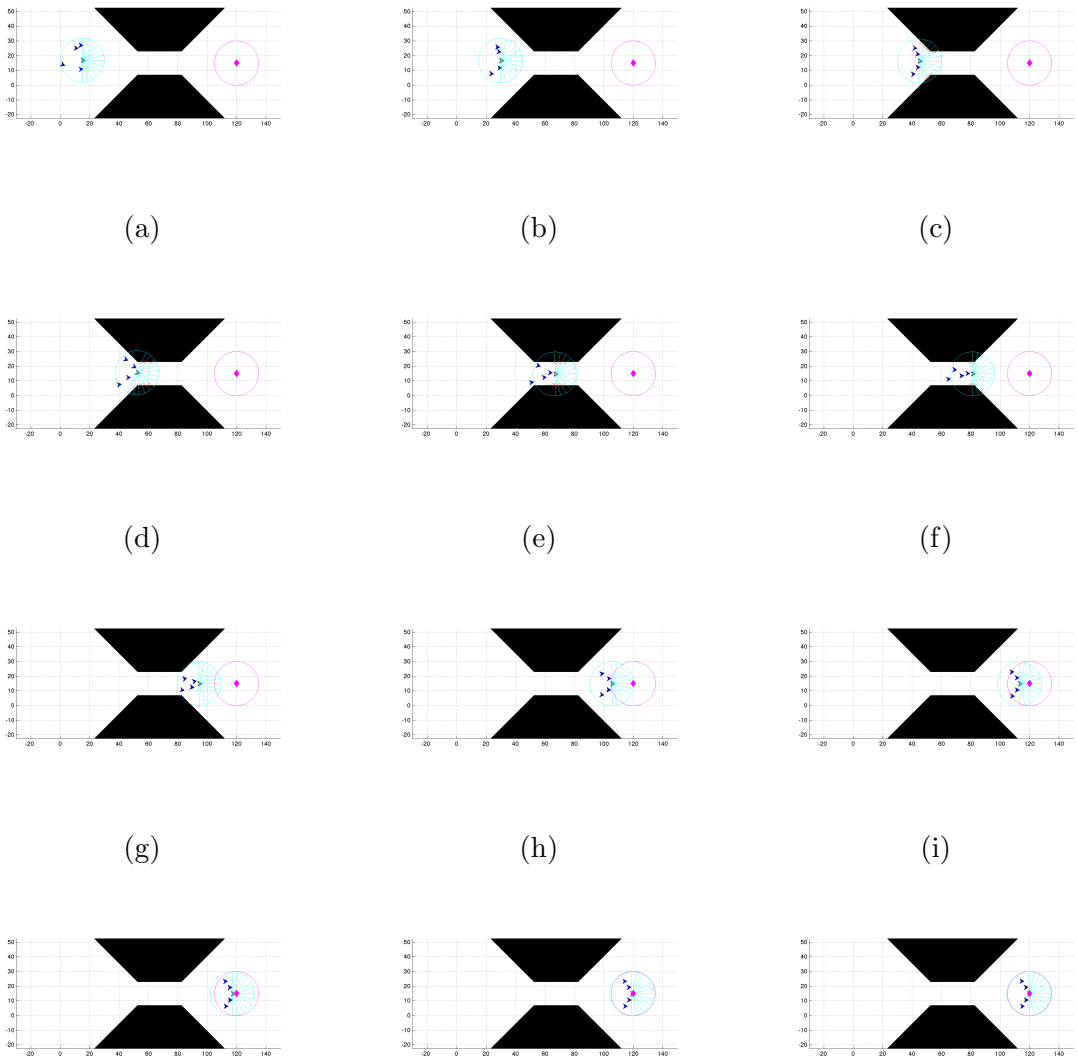
(g) (h) (i)

(j) (k) (l)

Figure 9.20: V-formation through a narrow passage

The leader robot determined the distance for the narrow passing using its sensor readings, and a desired V-angle was calculated for the group. The simulation

in figure 9.20 shows how the formation reconfigures to travel through the narrow passage, and then expands again when the obstacle is no longer in view.



(a) (b) (c)

(d) (e) (f)

(g) (h) (i)

(j) (k) (l)

Figure 9.21: V-formation through the narrowest passage

9.2.2.6 V-Formation Through a Very Narrow Passage

Finally the last simulation examined a V-formation through a very narrow passage. In this simulation (figure 9.21), the passage opening is only large enough for a single

robot to pass through at a time. In order to navigate the group through this difficult obstacle, the robots position themselves into a platoon to go through the passage, and then once the obstacle is out of view, the formation reconfigures to its initial V-shape.

9.2.3 Experimental Algorithm

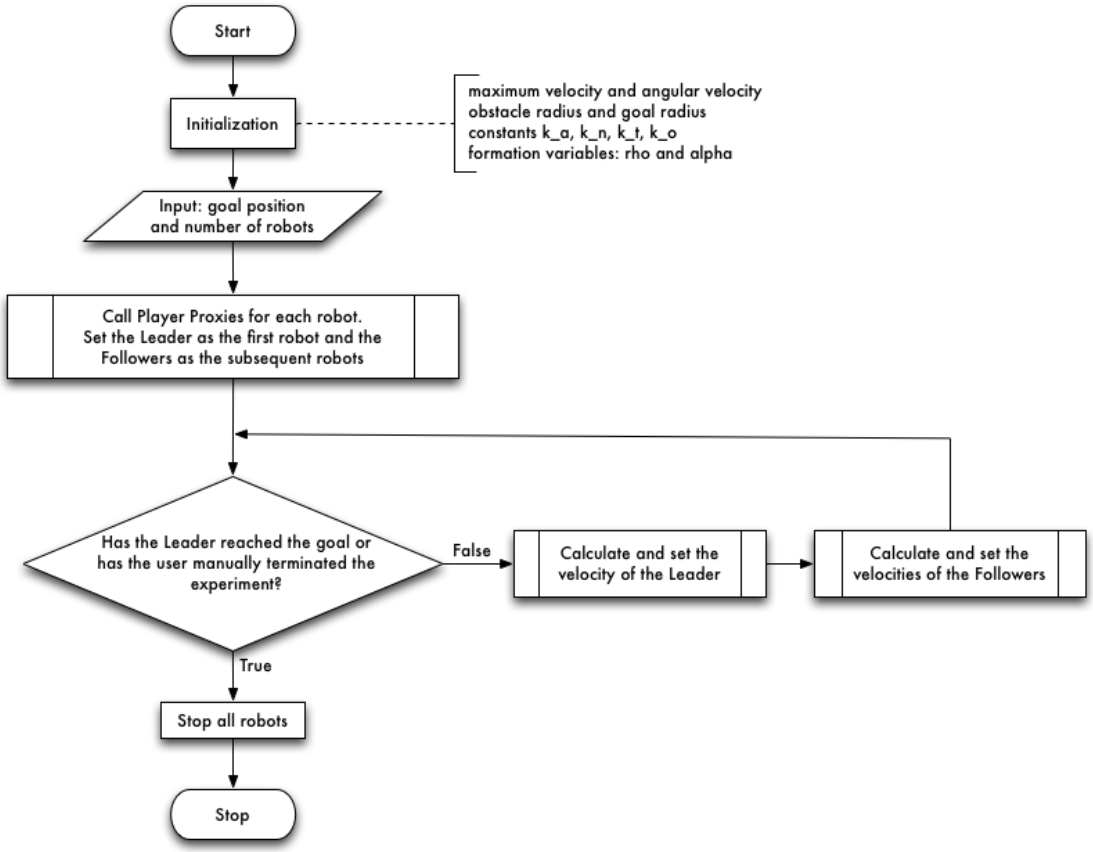


Figure 9.22: main function

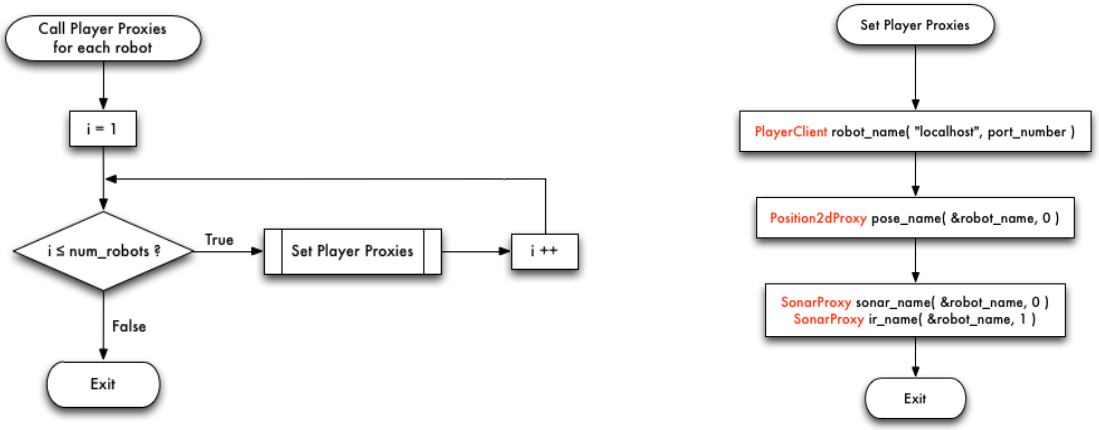
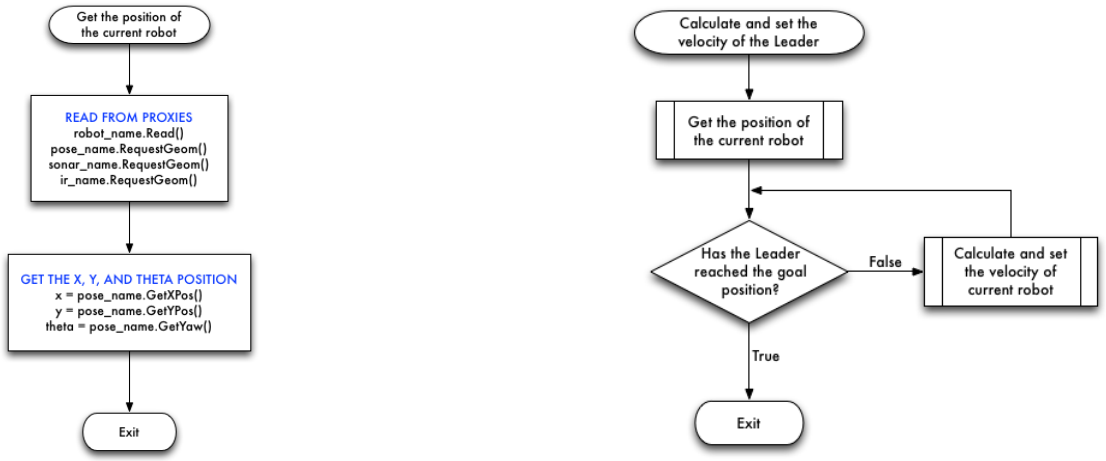


(a) (b)

Figure 9.23: (left) call player proxies, (right) set player proxies



(a) (b)

Figure 9.24: (left) get the pose of the current robot, (right) calculate the velocity of the leader

The experimental algorithm for the Leader-Follower formation with collision avoidance follows a similar procedure to the previous experiments. In the main function (figure 9.22), parameters are initialized and the Player Proxies are called for the leader and follower robots. The velocities of the leader and follower robots are calculated in the loop, and the loop continues until the leader has reached the goal position.

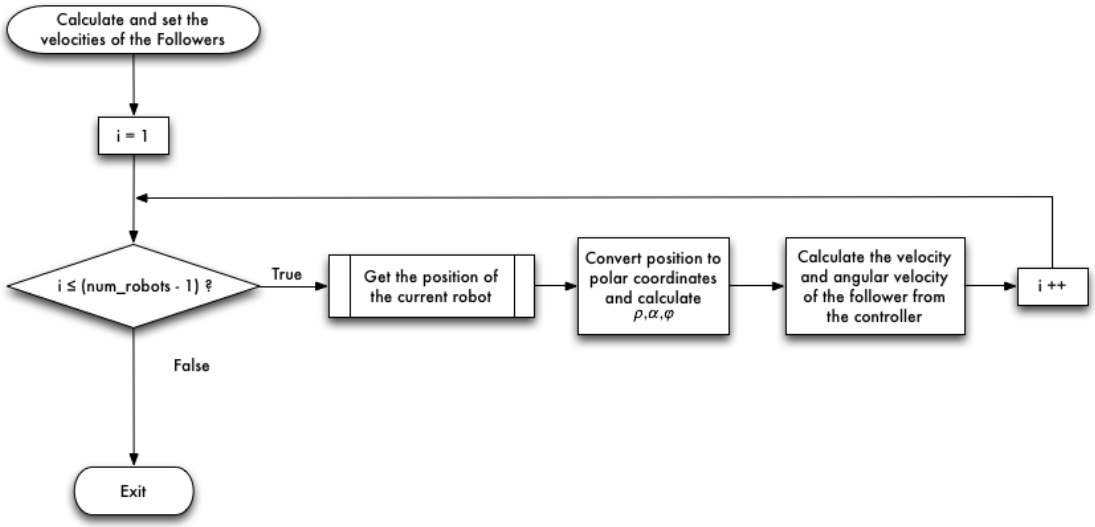


Figure 9.25: Calculate the velocities of the followers

The calculations for the leader and follower robots are displayed in figure 9.26a and figure 9.25. The leader employs a strategy where it checks for obstacles in the terrain and then calculates a navigation strategy through the obstacles. The follower robots rely on the following tracking controller to position the follower vehicles behind the leader at a desired distance and angle.

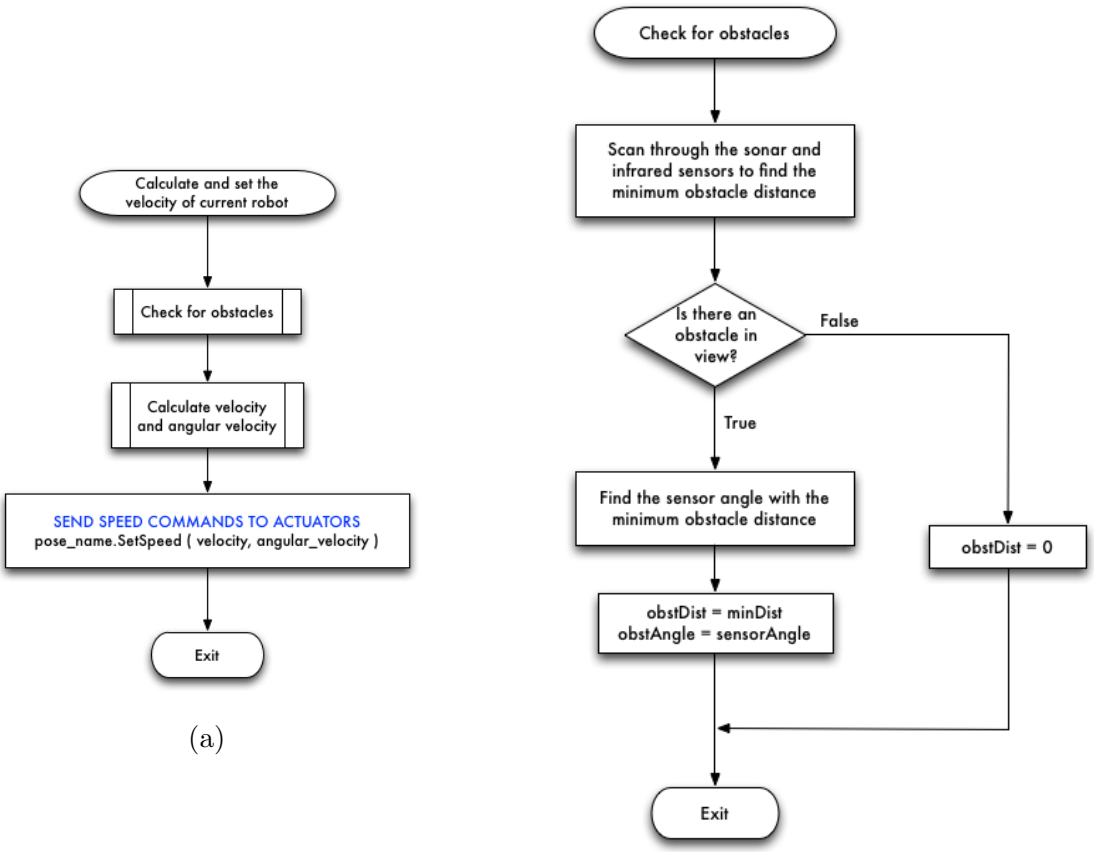

Figure 9.26: (left) calculate the velocity of the current robot, (right) check for obstacles

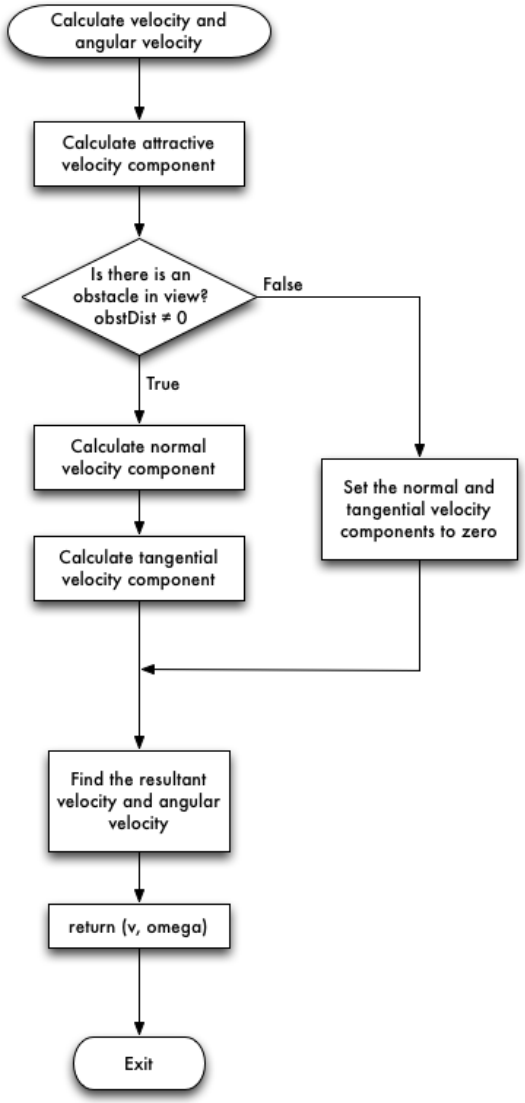

Figure 9.27: Calculate velocity and angular velocity

9.2.4 Experimental Results

9.2.4.1 Platoon Formation with Collision Avoidance

For the experiments with the X80 mobile robots, we first wanted to test a geometric formation navigating around an obstacle. A potted plant was used as the obstacle, and a platoon formation was chosen for the group. Using the LF formation with collision avoidance, the formation was able to successfully navigate around the obstacle and reach the goal position in front of the camera. The results for the formation controller with the X80 robots are shown in figure 9.28

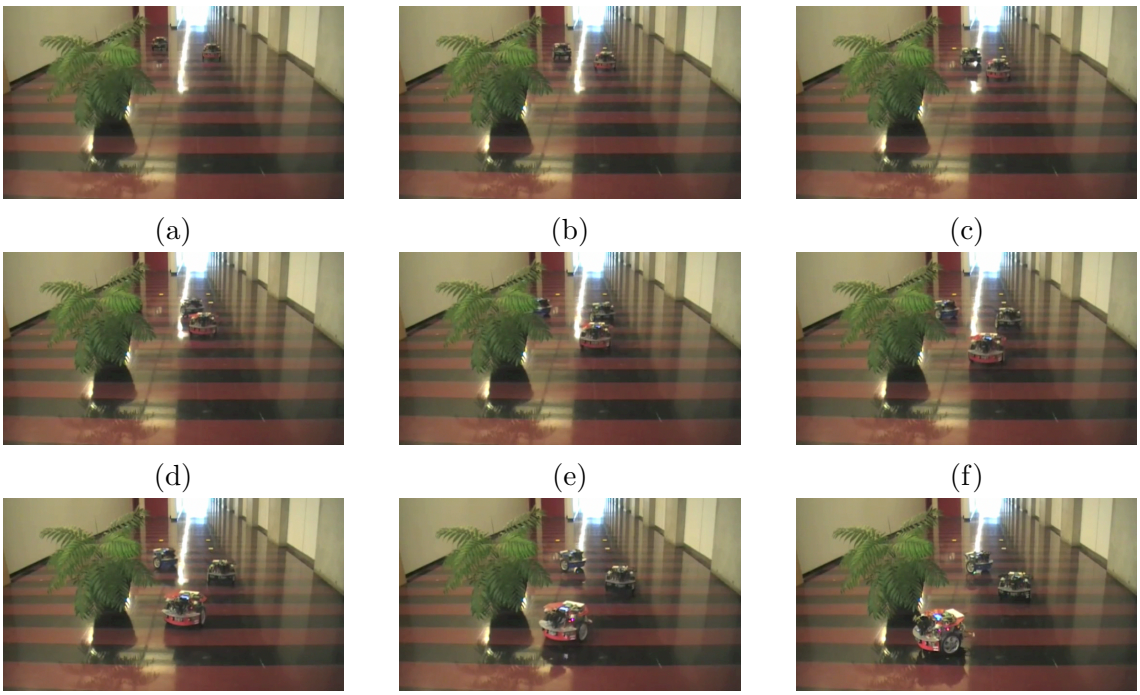

Figure 9.28: Platoon with an obstacle

9.2.4.2 V-Formation through a Narrow Passage

The next experiment tested the V-formation through a narrow passage. In this experiment, the passage distance was too small for all of the robots to travel through with their initial V-angles. Thus, as the leader passed through the narrow passage

it calculated the passage distance based on its sonar and infrared readings, and adjusted the V-angle to accommodate the group. Figure 9.29 shows the reconfiguring V-formation through a narrow passage.

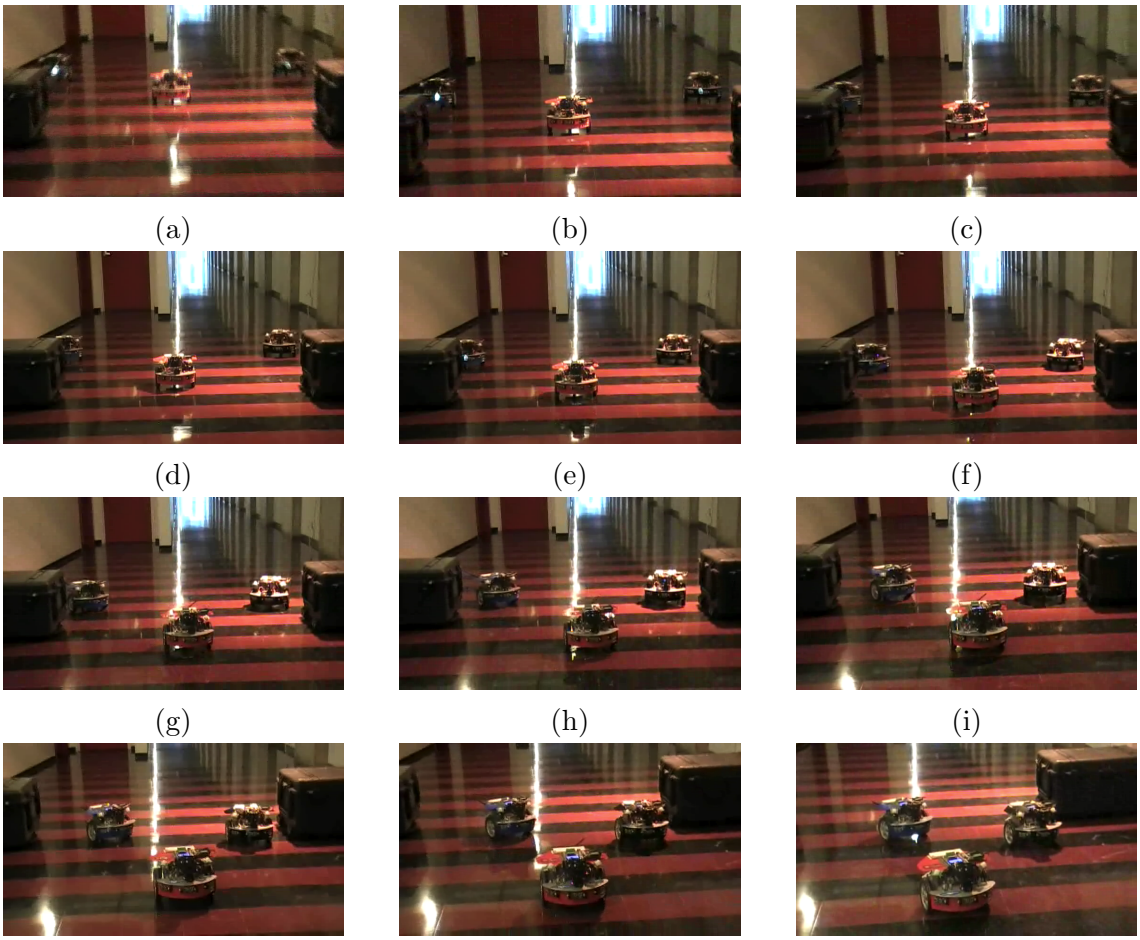

Figure 9.29: V-formation through a narrow passage

9.2.4.3 V-Formation through a Very Narrow Passage

Finally, the last experiment tested the V-formation through a very narrow passage. In this case, the passage distance is large enough for one robot to pass through at a time. Figure 9.30 shows how the angle of the V-formation decreases based on the calculated passage distance, and how the robots created platoon formation to navigate the group through the complex obstacle.

Chapter 10

Results for Self-Organizing Formations

In this final results chapter, we expanded the Velocity Potential (VP) method to a multi-robot scenario, to test its feasibility as a formation controller. Simulations were first conducted in MATLAB, however the multi-robot VP method was too computationally heavy for the MATLAB development environment, and the simulation experienced significant delays. For all self-organizing formation testing using the VP method, the Player/Stage simulation environment was used, since it supports multi-threading and is designed for multi-robot applications.

The following chapter describes the simulation and experimental work done to create self-organizing multi-robot formations using the Velocity Potential method. Section 10.1 explains the work done to develop a C++ file that automatically creates configuration and world files for large groups of robots. Section 10.2 explains the algorithm for the C++ self-organizing controller code. Finally, section 10.3 and section 10.4 describe the simulation and experimental work with the X80 robots for the self-organizing case.

10.1 Creating Configuration and World Files for Large Groups of Robots

The goal of our simulation work with the self-organizing formation was to test the Velocity Potential controller on a large group of homogeneous robots to see if they could navigate to a goal and avoids inter-robot collisions along its way. It was found that writing configuration and world files by hand for large teams of robots was a time consuming and error prone task. In order to make the self-organizing simulations scalable from a small group of robots to a very large group of robots, it was beneficial to create a C++ file to automatically generate the configuration and world files for any number of robots inputted by the user.

Appendix N contains the C++ code to automatically generate the configuration and world files. In the code, the user can update any of the parameters for the simulation, and the change is then applied globally to all of the configuration and world files. Creating this program improved the efficiency of the simulation development phase, and allowed us to test the VP self-organizing formation on any size of group.

10.2 Simulation Algorithm

The self-organizing simulation was programmed using object-oriented C++ programming concepts, and was designed to scale to any number of robots set by the user. The full code can be found in Appendix O and consists of seven files that all connect to the SelfOrganizing.cpp main function. The details of the main function are explained in the figure 10.1, and just like the simulations from Chapter 8 and Chapter 9, the self-organizing simulation initializes variables and acquires inputs form the user. It then calls on the Player Proxies to connect the robots to the PC over a wireless network. The simulation then calculates and sets the velocities of all

of the team members in a loop until one of the robots reaches the goal position. Figure 10.2a and figure 10.2b show how the controller sets the proxies for any number of robot.

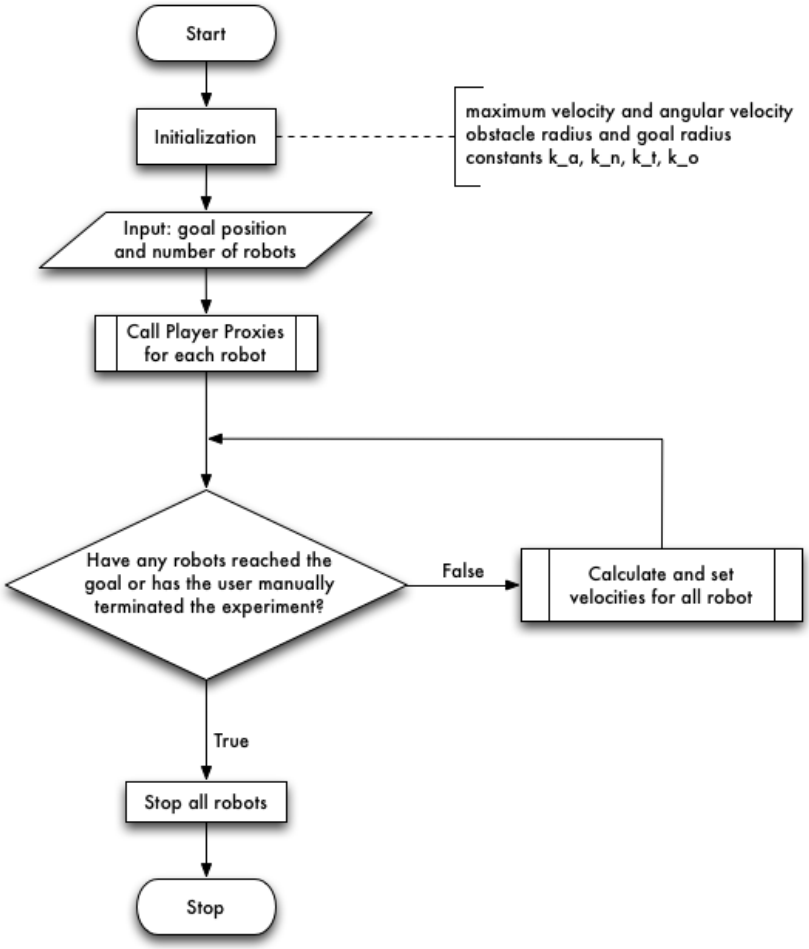

Figure 10.1: Main function

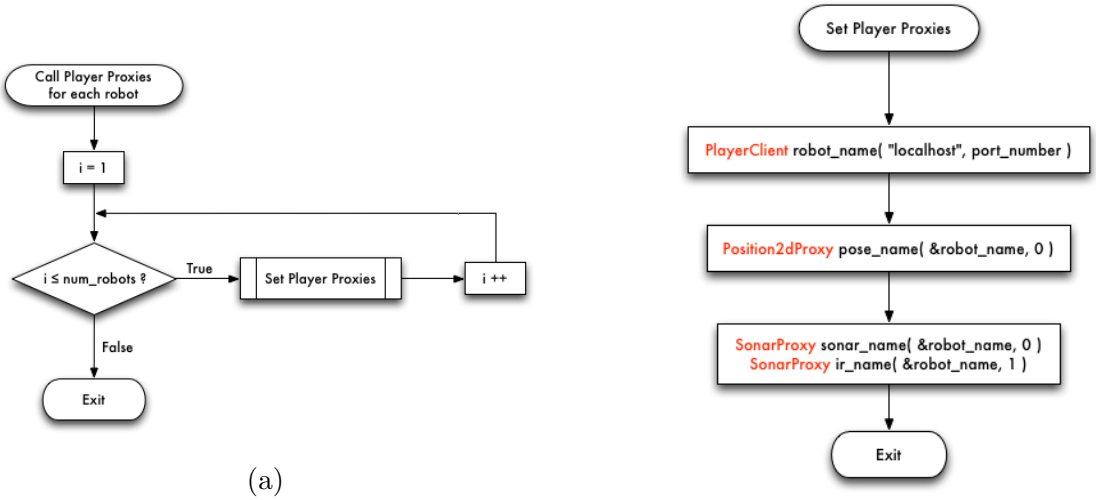

Figure 10.2: Set player proxies

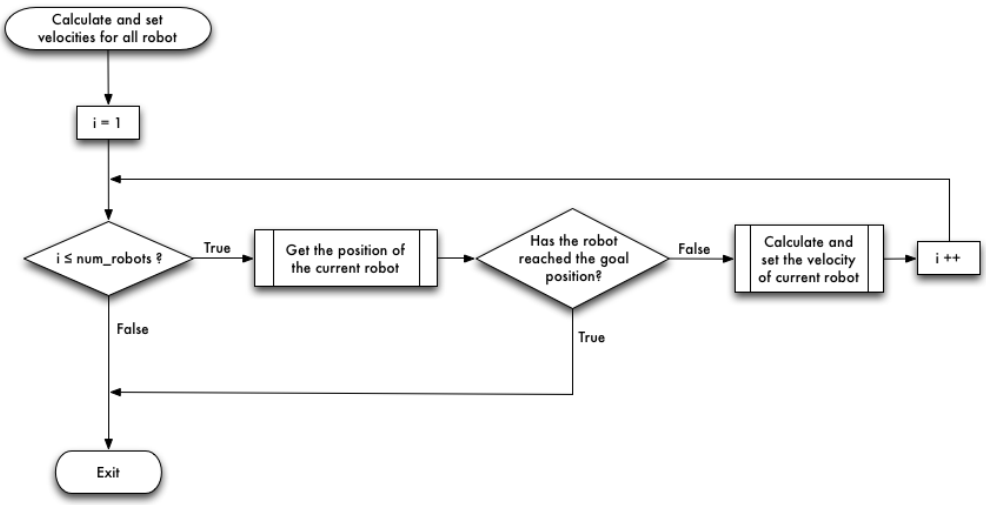

Figure 10.3: Calculate velocity

Figure 10.3 shows the steps required to calculate the linear and angular velocity for each robot. First the current pose of the robot is determined based on the methodolgy of figure 10.4a. If the robot has not reached the goal position, the velocity of the current robot is calculated based on the methodology of figure 10.4b, that checks for obstacles (figure 10.5a) and calculates linear and angular velocity (figure 10.5b) based on the equations from the Velocity Potential method.

The velocity calculations of figure 10.3 are looped until each robot calculation is carried out. Velocity commands are set using the SetSpeed() method, and when the a robot has reached the goal position all of the vehicles are stopped and the simulation ends.

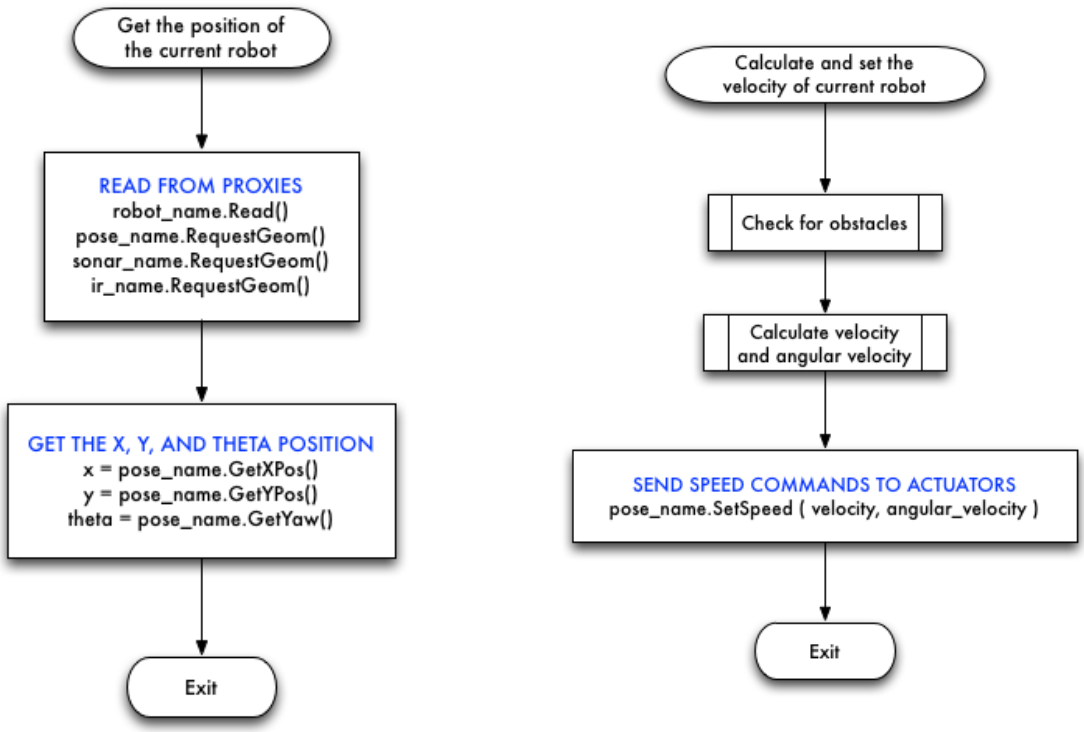

Figure 10.4: (left) get current pose, (right) set velocity

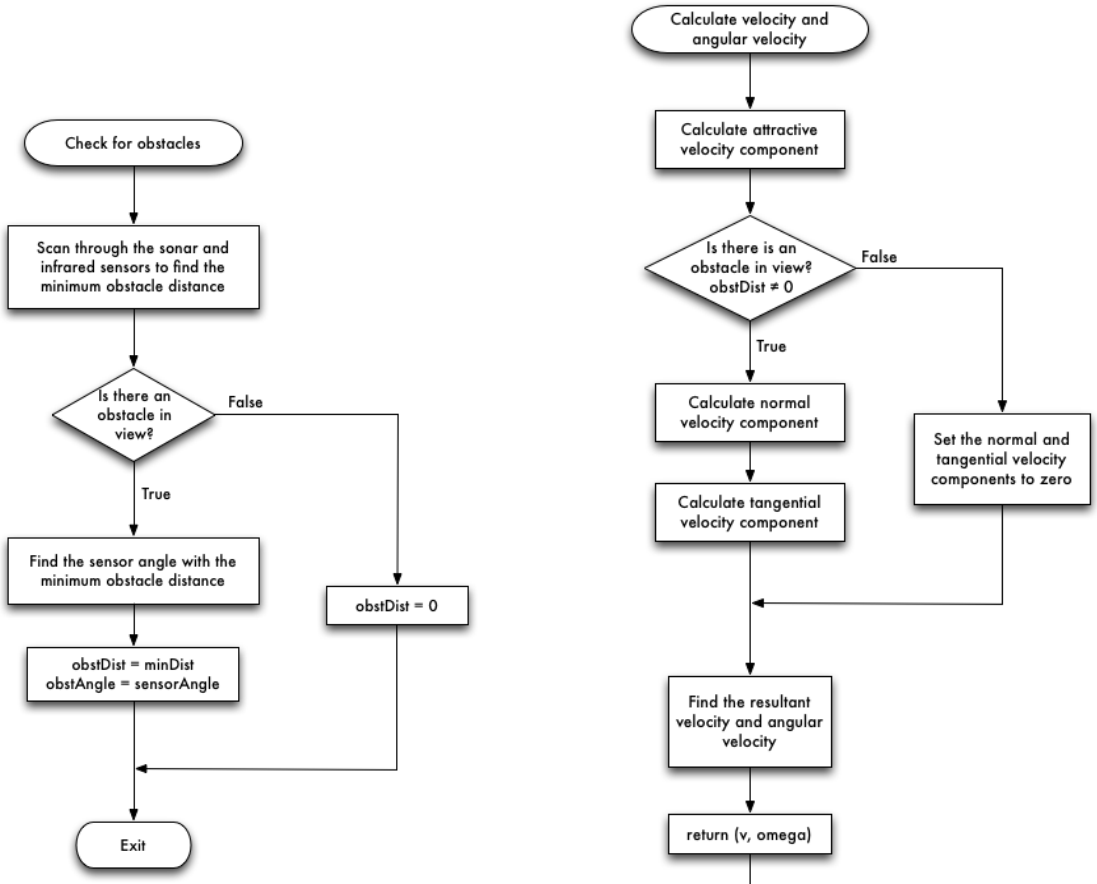

Figure 10.5: (left) check for obstacles, (right) calculate velocity and angular velocity

10.3 Simulation Results

10.3.1 Three Robots

The first simulation tested the Velocity Potential controller on a group of three robots. All robots were able to successfully navigate towards the goal without any collisions. By incorporating the velocity potential method, each robot created a safety zone around its body that kept the other robots safely away. Figure 10.6 shows snapshots of the self-organizing simulation with three robots.

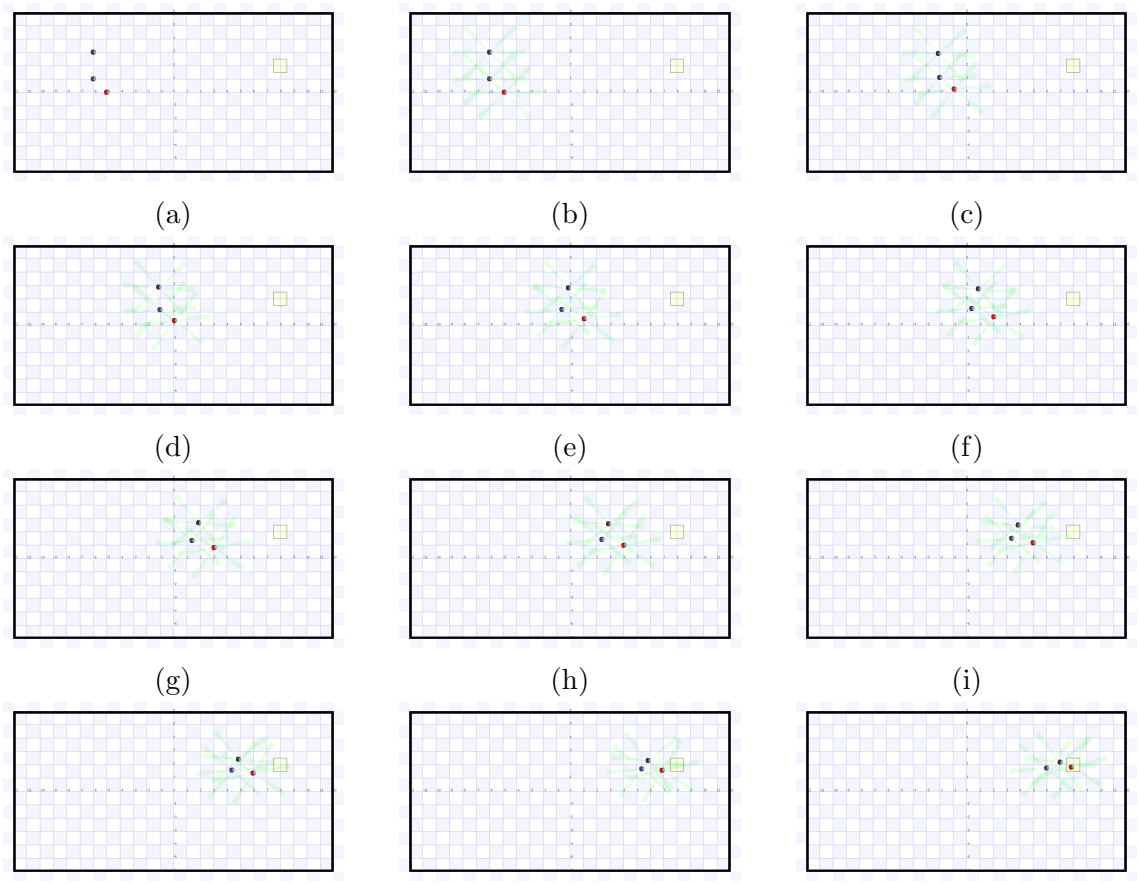

Figure 10.6: 3 Robots

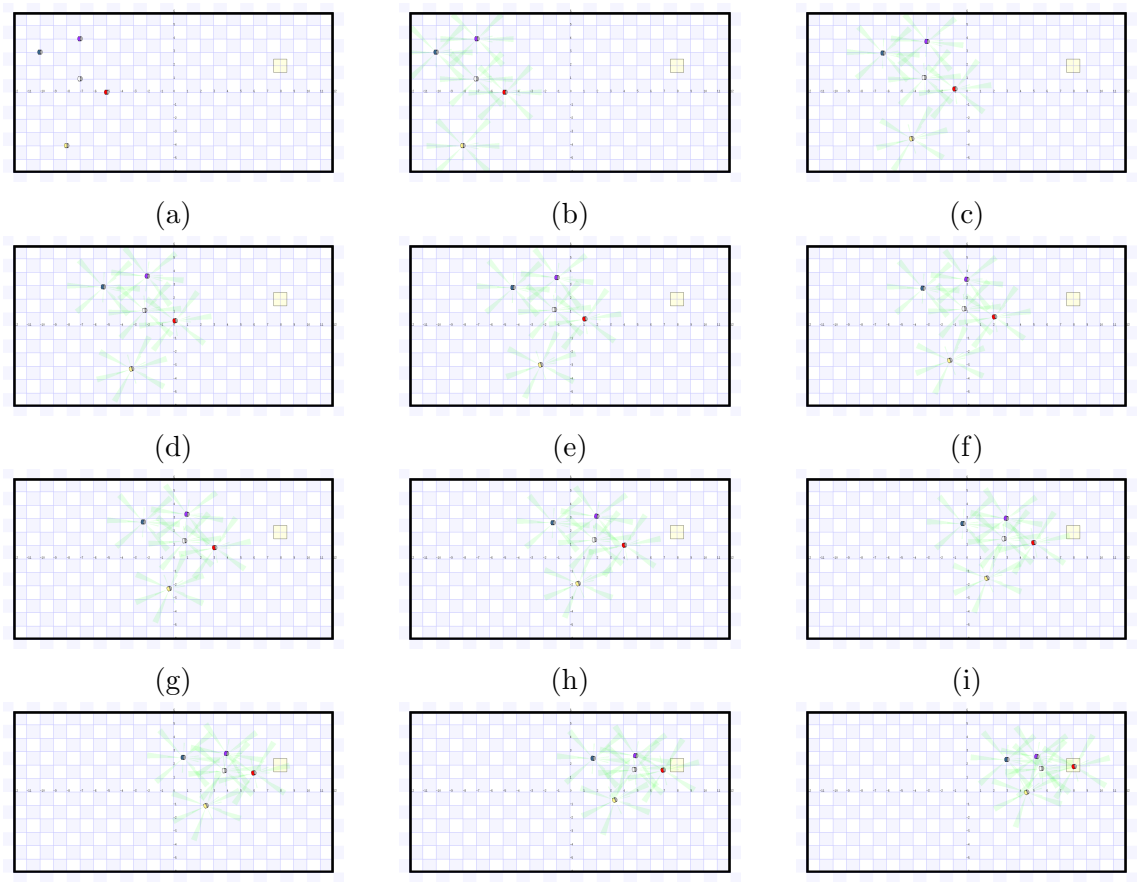
10.3.2 Five Robots

In the next simulation we increased the number of robots in the terrain to five robots. All of the robots are attracted to the same goal position, and the simulation ended when one of the robots reached the goal position. Figure 10.7 shows snapshots of the simulation with five robots.



(a) (b) (c)

(d) (e) (f)

(g) (h) (i)

(j) (k) (l)

Figure 10.7: 5 Robots

10.3.3 Eight Robots

The third simulation expanded the self-organizing case to eight robots. With eight robots, the group is more crowded than the three or five robot simulation, but the Velocity Potential method holds up, and the group is able to successfully navigate towards the goal position. Figure 10.9 shows snapshots of the simulation with eight robots.

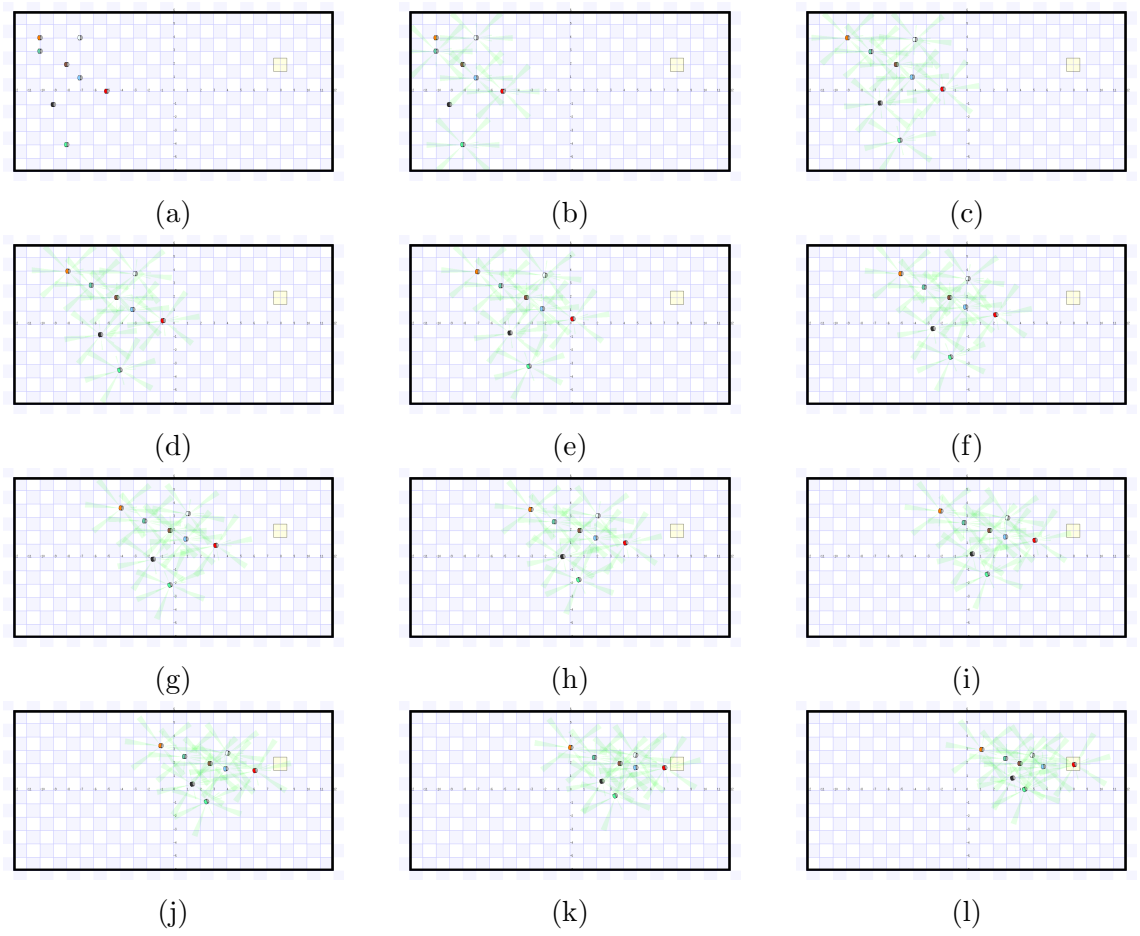


Figure 10.8: 8 Robots

10.3.4 Twelve Robots

In the fourth simulation, we expanded the group to twelve robots. With twelve robots the self-organizing VP group looks quite a bit like a swarm formation seen in the literature. As the robots travel towards the goal formation elongates since all of the robots are trying to reach the same goal position. Figure 10.9 shows snapshots of the self-organizing simulation with twelve robots.

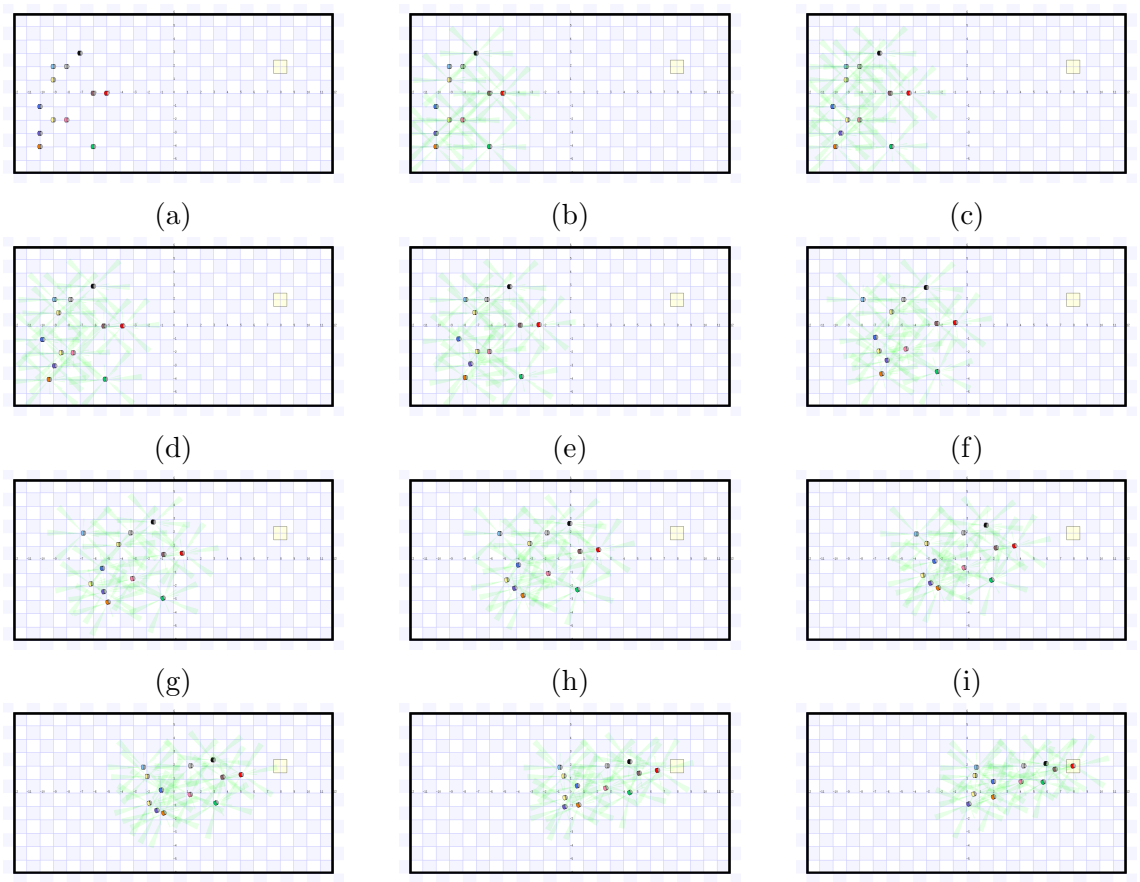

Figure 10.9: 12 Robots

10.3.5 Twenty Robots

Finally, the last simulation looks at a large team consisting of 20 mobile robots. As in the twelve robot case, the formation elongated as the robots navigated towards

the goal position. Since the twenty robot simulation had many team members, the formation created a triangle shape towards the rear of the formation, since the back team members needed to slow down in order to avoid colliding with the robots at the head of the formation. Figure 10.10 shows snapshots of the self-organizing formation for a team of twenty mobile robots.

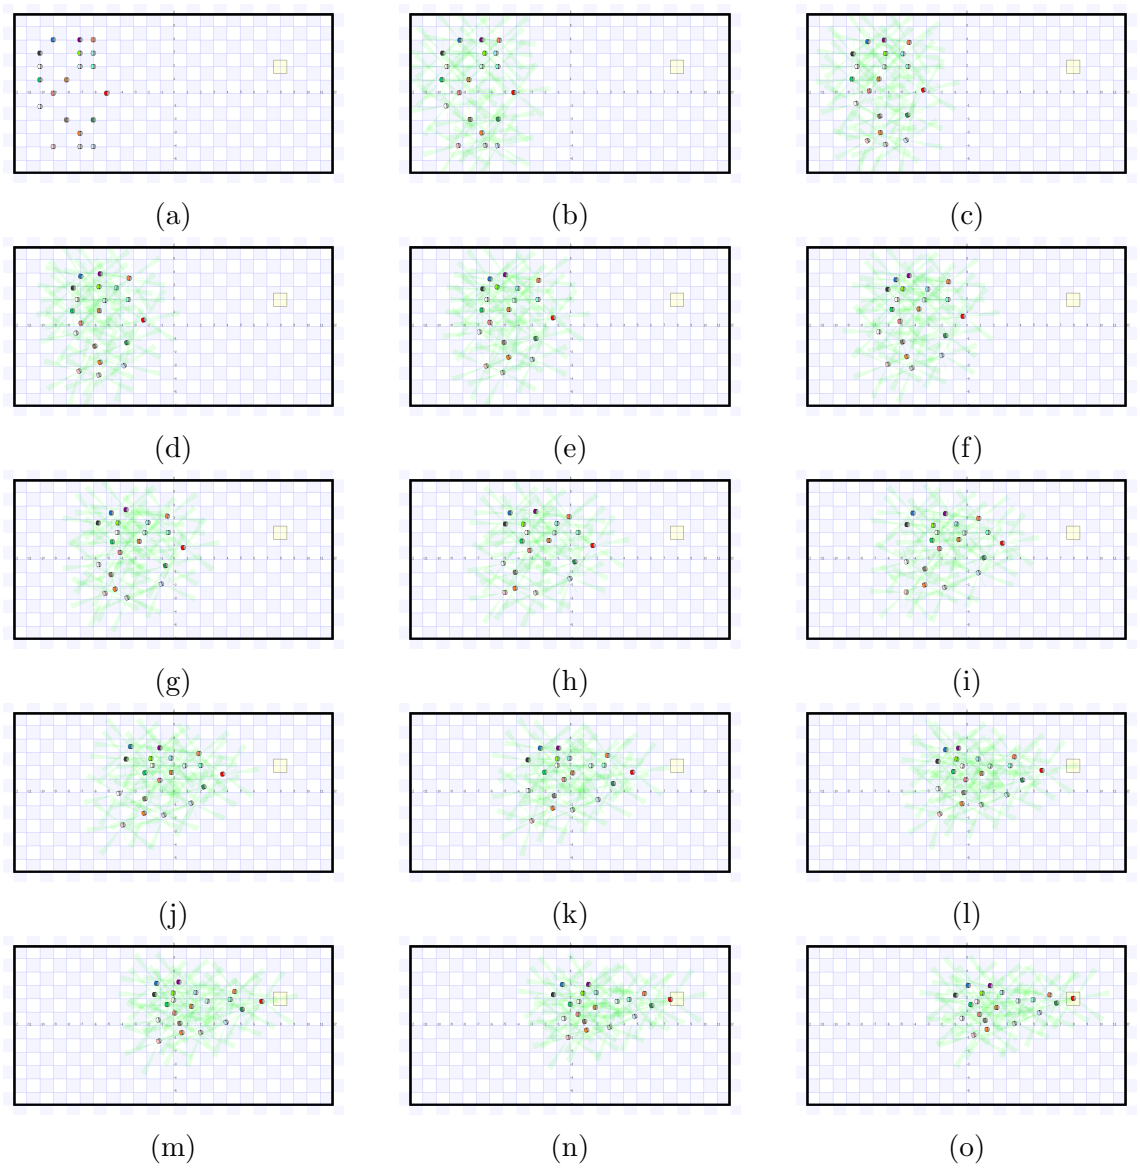

Figure 10.10: 20 Robots

10.4 Experimental Results

In the experiments with the X80, we wanted to test the Velocity Potential self-organizing formation on three robots. In the first experiment, the three robots we placed in a terrain without obstacles. Using the self-organizing formation approach, the robots navigated towards the goal position in front of the camera, while keeping a safe distance from each other. Figure 10.11 shows snapshots of the experiments with no obstacles in the terrain.

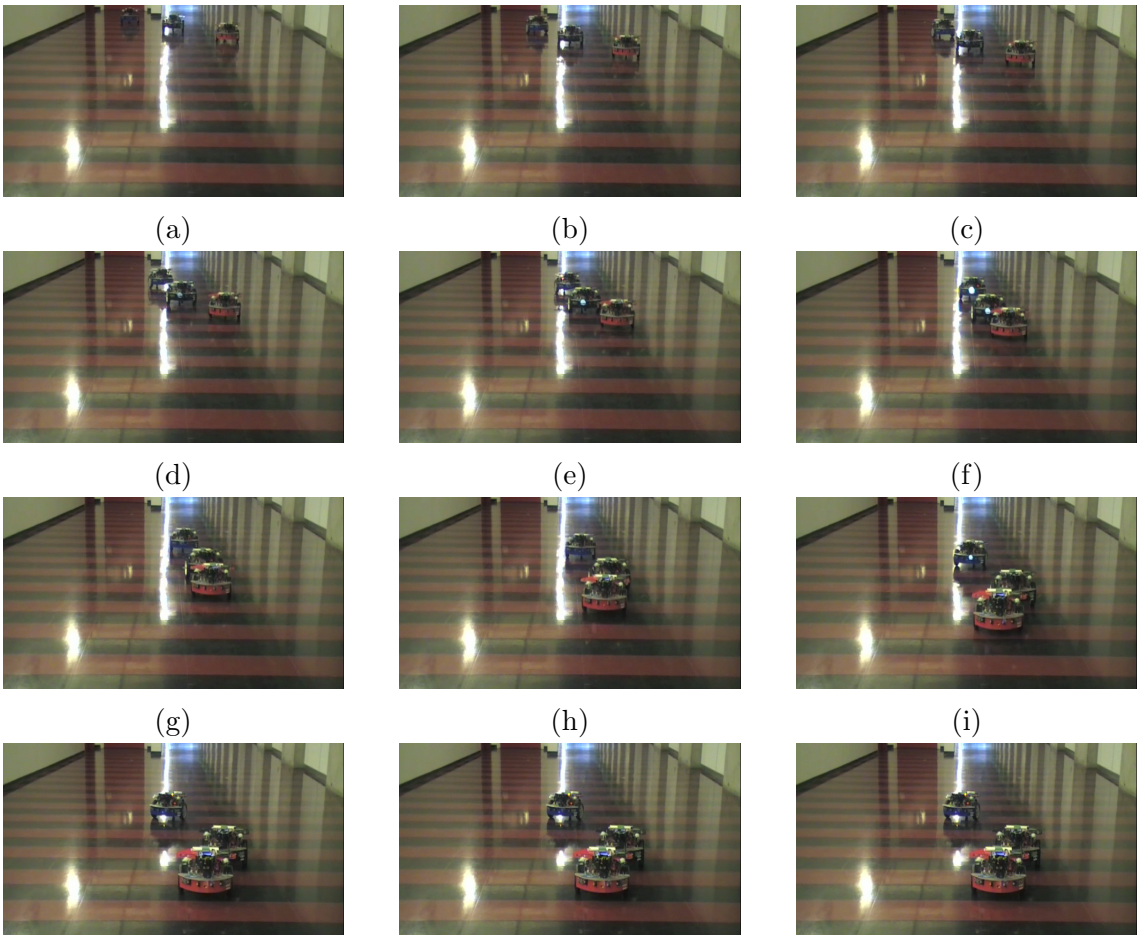

Figure 10.11: Self-organizing no obstacle

Finally, the last experiment with the X80 mobile robots added an obstacle in the terrain. The obstacle was a potted plant, and it was placed in the path between the initial pose of one of the robots and the goal position. Using the self-organizing velocity potential approach, the robots were able to avoid a collision with the obstacle in the terrain. Moreover, the other two robots adjusted their movement, and all three robots navigated around the obstacle as a unit, while keeping a safe distance from each other. Figure 10.12 shows the self-organizing formation around an obstacle in the environment.

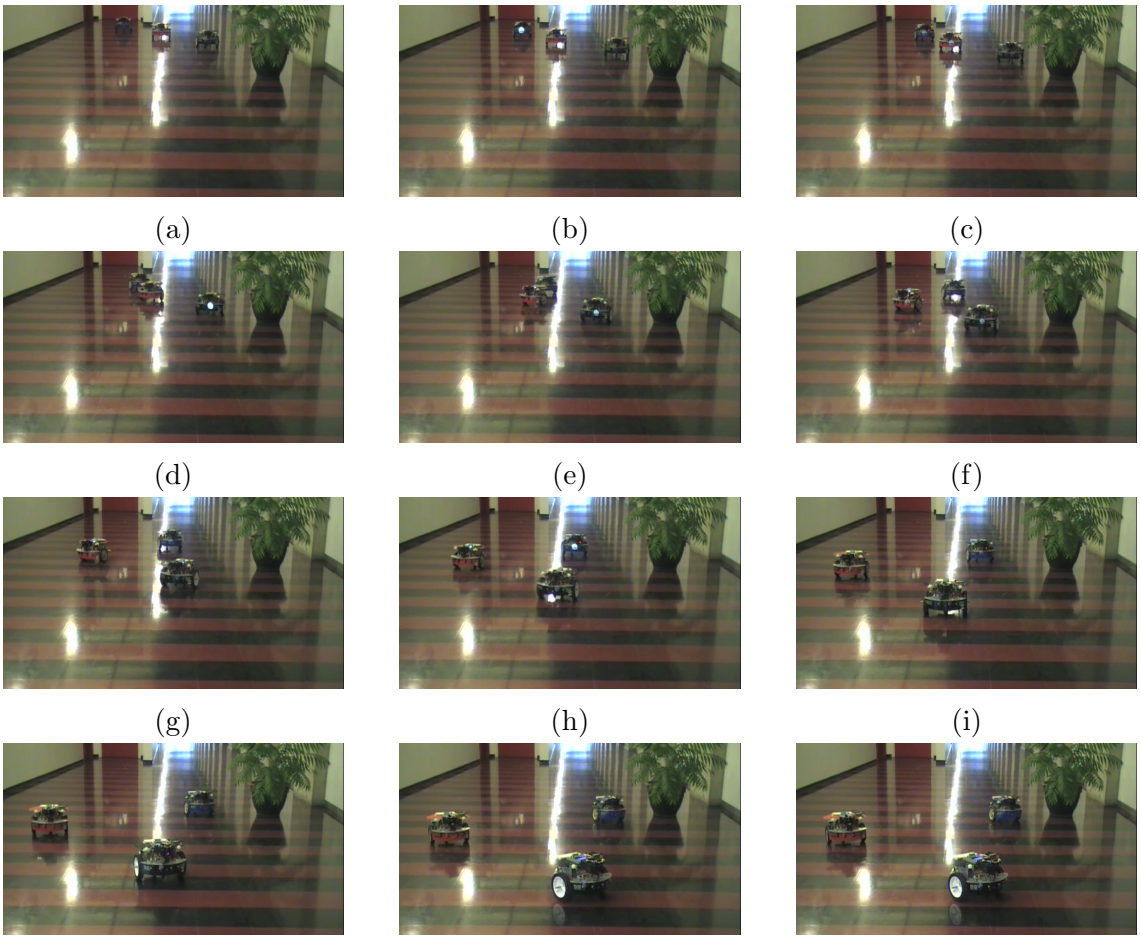

Figure 10.12: Self-organizing with an obstacle

Chapter 11

Conclusion

The purpose of our research work was to develop a navigation and formation control strategy to move a team of robots through a two-dimensional terrain to a goal position without colliding with obstacles in the environment. In order to solve the motion planning problem, we developed a Velocity Potential navigation controller. The navigation controller was inspired by the velocity potential function in fluid mechanics, and modeled the flow to the goal as a uniform flow field, and the flow around the obstacle as a spiral vortex. Simulations and experiments using the velocity potential controller were carried out in MATLAB and Player/Stage, and the experiments tested the algorithm in environments with simple and complex obstacles. The velocity potential navigation controller successfully navigated a single robot around all obstacle geometries.

After developing a navigation strategy for the team of robots, formation controllers were developed to coordinate the members of the group. A leader-follower formation controller was chosen, where the leader would navigate through the terrain using the navigation controller, while the followers would orient themselves at predefined positions behind the leader. Two different leader-follower geometries were created: (1) platoon formation, and (2) V-formation. In our experiments we

first tested how the robot formations would develop in a terrain with no obstacles. We then placed the formations in a terrain with obstacles, and applied a reconfiguration strategy, so that the platoon or the V-formation could adapt its formation shape to the obstacles in the terrain. The reconfiguration property was essential in the design of the leader-follower controller, so that the group could navigate around difficult obstacles, without any collisions with obstacles in the terrain. Simulations for the reconfiguring leader-follower formations were carried out in MATLAB, and the experiments with Player/Stage tested the formation on 3 X80 robot units.

Finally, in our last simulations and experiments we expanded the velocity potential method, and allowed the robot movement to be defined in a distributed decentralized manner by the velocity potential controller. The multi-robot velocity potential controller created a self-organizing formation, where robots on the team would orient themselves in order to reach the goal, but also not collide with each other along the path. Simulations for the multi-robot case were carried out on 3, 5, 8, 12, and 20 robots, and experiments with the X80 robot were carried out on 3 robot units.

11.1 Research Contributions

The proposed methods improved upon the artificial potential field navigation controller for self-organizing systems. The artificial potential field methods struggled from the local minimum problem, and had difficulties navigating around complex obstacles, such as the concave obstacle and the narrow passage obstacle. Used as a navigation controller, the velocity potential flow controller was able to easily navigate a robot around these complex obstacles. Furthermore, when the velocity potential flow controller was scaled to large multi-robot systems, the team was able to move through the environment like a swarm formation. Our research contributed to the

domain of swarm systems, and provided a new mechanism of self-organization to a group of distributed decentralized robots. Finally, the reconfiguring leader-follower controller, along with the velocity potential navigation controller, showed that a team of mobile robots could travel through the terrain in a desired geometric formation, and its formation shape could morph and adapt to changes in the environment, so that the formation could handle complex obstacles in dynamic environments.

11.2 Future Work

The next phase in the project is to increase the level of coordination and inter-robot collision avoidance. In our geometric formation control experiments with the leader follower method, the follower robots were assigned positions at an adequate distance and angle from the leader and each other in order to avoid inter-robot collisions. Although this method did provide good results for group coordination, it is not a global solution to the overall formation control problem. The next step in this research is to provide a mechanism for inter-robot collision avoidance for the follower robots while they travel in the leader-follower formation.

Furthermore, there are still work that needs to be addressed in the self-organizing formation case using the velocity potential method. The self-organizing formation was never tested on complex obstacles like the concave obstacle and narrow passage. The added confined space requires modification to the parameters of the self-organizing controller. The long-term goal for the velocity potential method and leader-follower formation controller is to develop a global solution to the navigation and formation control problem, where the overall movement of the team is adaptable to any environment that the team will face.

Appendix A

How to Install Player/Stage

Player and Stage work together to operate mobile robots from a Unix based operating system such as Linux or Mac. Player is a hardware abstraction layer that provides access to the robots sensors and actuators for real robot testing. Stage is a 2-dimensional simulation software. Within stage you set up the geometry of the robot, what sensors are onboard, where the sensors are located on the robot, and any obstacles situated in its environment.

The largest benefit of using the Player and Stage software is the quick and easy transition from simulation to testing. Control of the robot movement is achieved with a C++ file that access values from sensor data and apply actuator control. The controller runs in parallel to Player, and is implemented in the same manner in either simulation or testing mode.

The goal of this appendix is to go through all of the steps needed to run a simulations and tests with multiple robots. The appendix will start with installation instructions for Player, Stage, and Eclipse. After installation is complete, the manual will then outline the steps of creating controllers in C/C++ in the Eclipse IDE, and how to run the code with the robots using the Terminal.

A.1 Operating System

Player and Stage can be installed on any Unix based operating system. The most popular operating system is Ubuntu from Linux. Player is a difficult program to install, expect a full afternoon to make the installation work perfectly. The safest bet is to install Player in Ubuntu since there is a big online community available to give advice if the install is unsuccessful. It is also possible to install Player on the Mac OSX, however a successful installation is more difficult than in Ubuntu.

Create a Linux partition on your computer and install the newest version of Ubuntu from

http://ubuntu.com/download

A.2 Installing Player and Stage

The robot drivers were programmed to work with Player version 2 and Stage version 3. Although there are newer versions of Player and Stage is available, changes must be done to the drivers for the robots to connect with these newer versions of the Player software. Hence for a quick transition it is suggested to install Player 2.x and Stage 3.x

You can get the .tar files for the installation from:

http://playerstage.sourceforge.net

Install Player version 2 first. Follow directions from the online community on how to complete the install. The success of the installation depends on your version of Ubuntu. If the installation is not successful on your first try, it is likely that the installation is missing components. Do an online search for common installation dependencies, install these dependencies, and then try the Player install again.

Repeat the procedure until Player is successfully installed onto your computer. After Player is working, install Stage. If there are problems while installing stage, check for installation dependencies, and try installing Stage again.

A.3 Testing Player and Stage

To test the Player and Stage installation we will use the Terminal window. Go to:

Applications → *Accessories* → *Terminal*

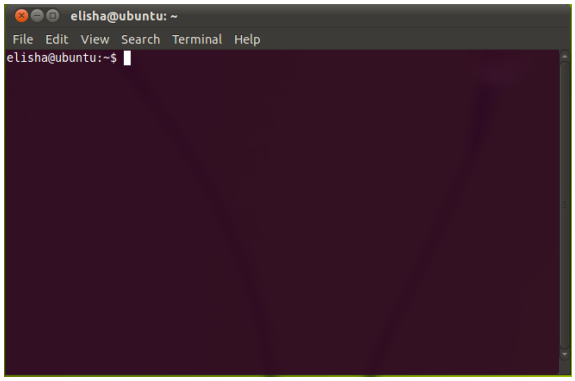

Figure A.1: Ubuntu terminal window

Use the ls command in the terminal to list options. Use the cd command to open folders. Find the location of the file simple.cfg.

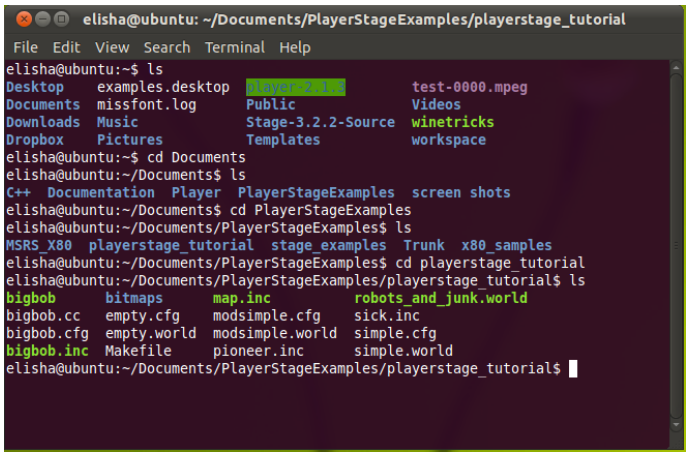

Figure A.2: Accessing Simple.cfg in the terminal

To start the simulation, use command to start the test simulation

player simple.cfg

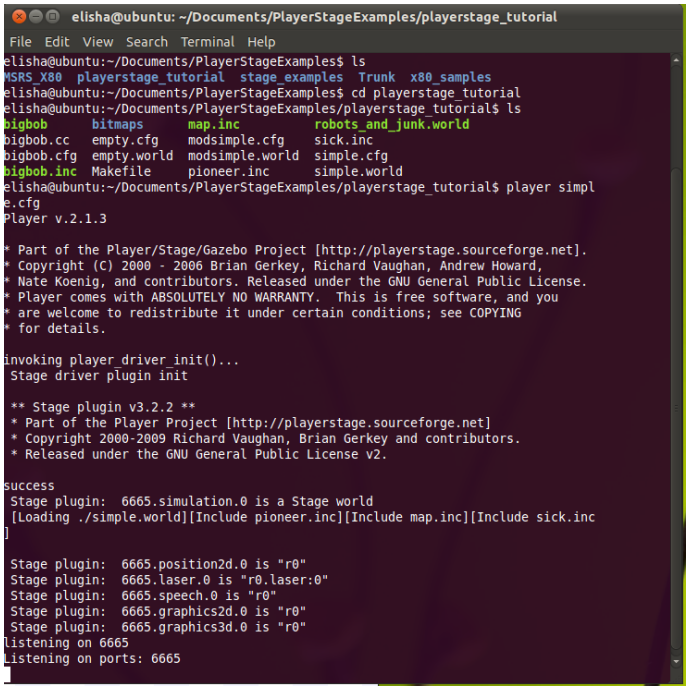

Figure A.3: Starting the simulation

If the simulation simple.cfg is running, then the installation was successful. A picture of the simulation window is displayed below.

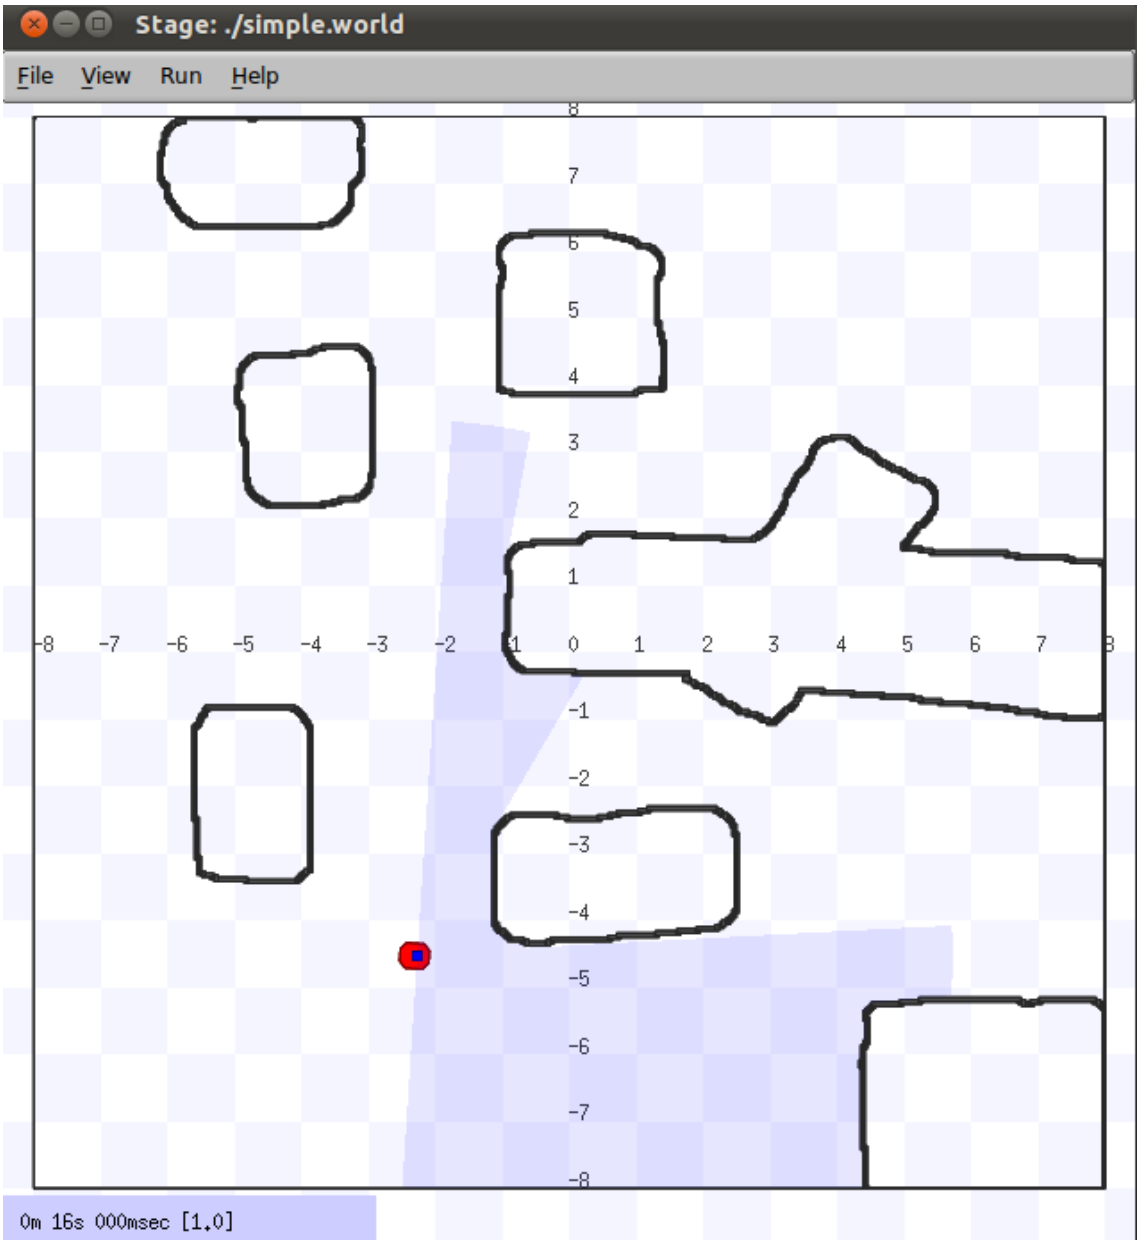

Figure A.4: A running simulation

Appendix B

How to Configure Eclipse to Access Player Libraries

B.1 Installing Eclipse CDT

Eclipse is the most popular development environment in Ubuntu. Programming your robot controllers in Eclipse will save you time and energy. Although there are many other development platforms in Ubuntu, Eclipse has the most support for Player and Stage.

Player controllers can be programmed in C/C++ or Python. Eclipse is generally used by Java programmers, and the general install has no C/C++ functionality. Hence a special version of Eclipse must be installed that has C/C++ functionality, this version is called Eclipse-CDT. To install Eclipse-CDT go to:

$$Applications \rightarrow UbuntuSoftwareCenter$$

In the search textbox write *eclipse-cdt*, double click on *C/C++ Development Tools for Eclipse* and follow installation directions.

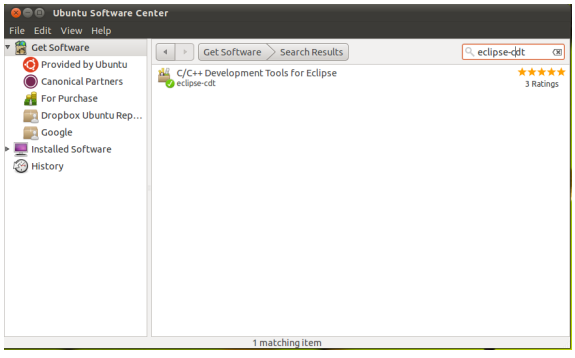

Figure B.1: Installing Eclipse from Ubuntu Software Center

B.2 Linking Eclipse to Player C/C++ Libraries

Every time you start a new project you need to link Eclipse to the Player C/C++ Libraries. The Player libraries include methods and attributes that are important to robot movement such as sensor and motor commands. Eclipse needs to know where this library is located on your hard drive so that it can access it when build the controller. Below is a step-by-step procedure on how to link Eclipse with Player.

- *file* → *newproject*
- call the project *example_setup*
- if you use *Hello World C++ Project*, Eclipse adds some basic start-up elements to the file

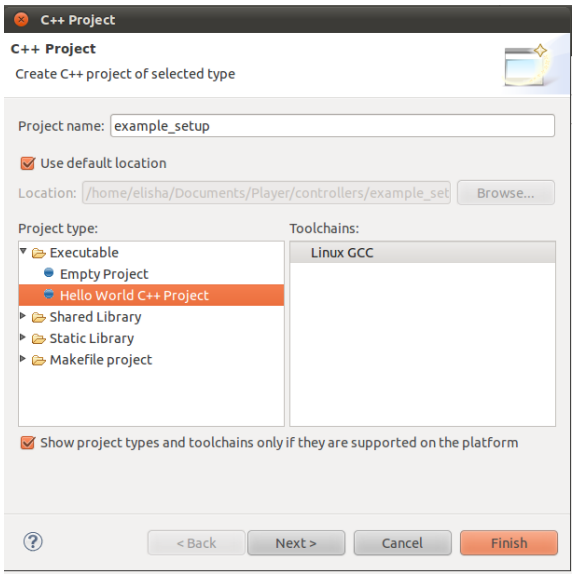

Figure B.2: Creating a new C++ project

- Now in the *Project Explorer* window on the left-hand-side of the screen, the *example_setup* project is displayed, and a cpp file with the same name, example_setup.cpp, is located in the source, src, folder within the project.
- For continuity, all c++ files for the robot control will be in the source folder

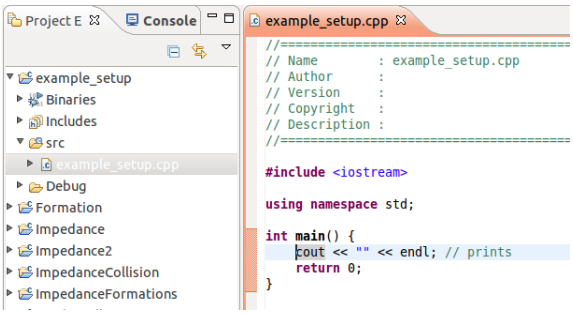

Figure B.3: Initial C++ file layout

- If you are using c++, do # include libplayerc++/player++.h
- If you are using c, do # include libplayerc/playerc.h
- Notice the yellow underline, Eclipse does not know what this library is or where it is stored. You need to add this library manually

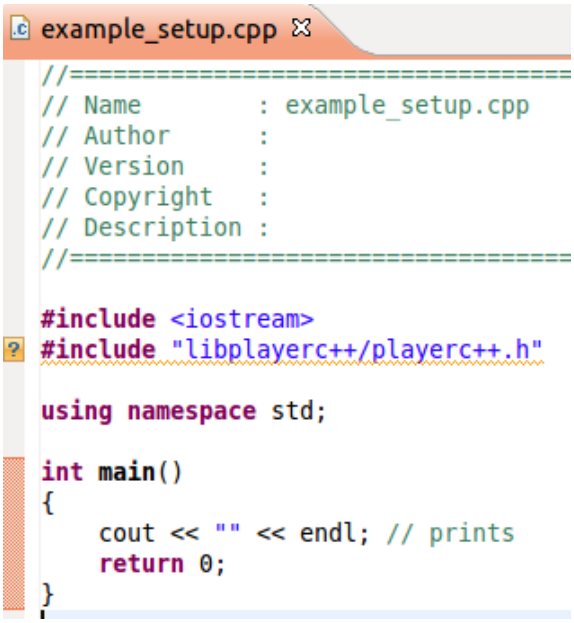

Figure B.4: Include the libplayerc++ library

- Go to *Project* → *Properties*

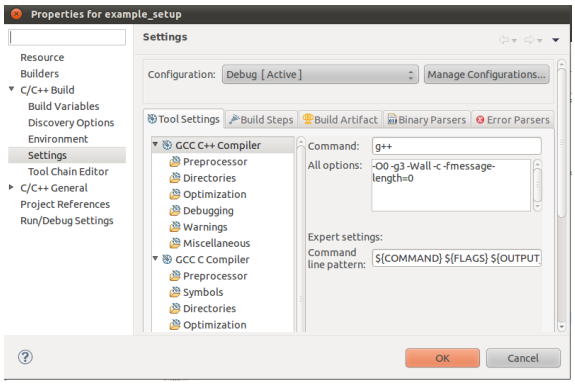

Figure B.5: Project Settings 1

- Under *C/C++ Build*, in *Settings* adjust *Tool Settings*

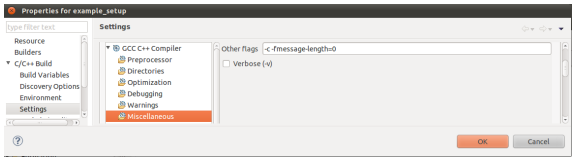

Figure B.6: Project Settings 2

- Under *GCC C++ Compiler*, click on *Miscellaneous*
- Add in the following line, exactly as written, in the *Other flags* text box

‘pkg-config –cflags playerc++‘

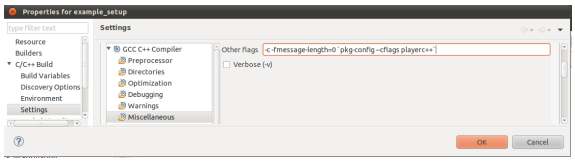

Figure B.7: Project Settings 3

- Press OK
- Scroll down to *GCC C Compiler*, and go to *Miscellaneous*
- Add in the following line, exactly as written, in the *Other flags* text box

‘pkg-config –cflags playerc‘

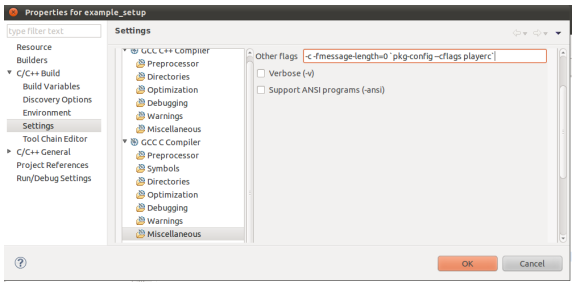

Figure B.8: Project Settings 4

- Under *GCC C++ Linker*, add in the following exactly as written in the *Linker flags* text box

‘pkg-config –libs playerc++‘

- After completing all of the above steps, press OK

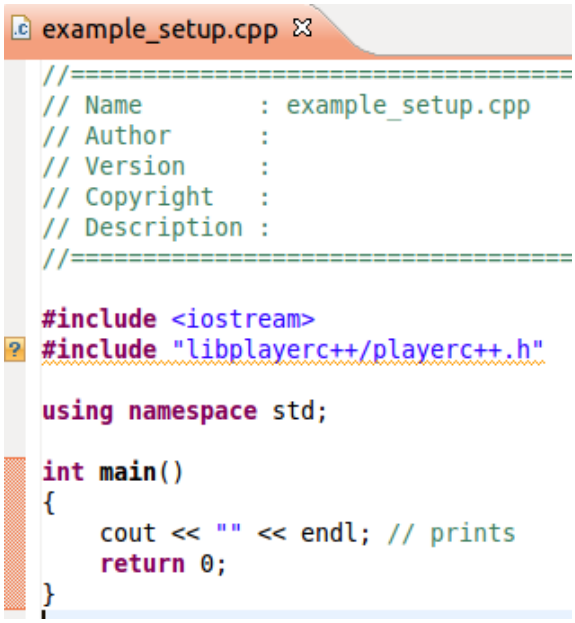

Figure B.9: Controller window

If there is still a yellow underline under # include libplayerc++, then the compiler does not know the location of the libraries. To fix this go back to Project-Properties

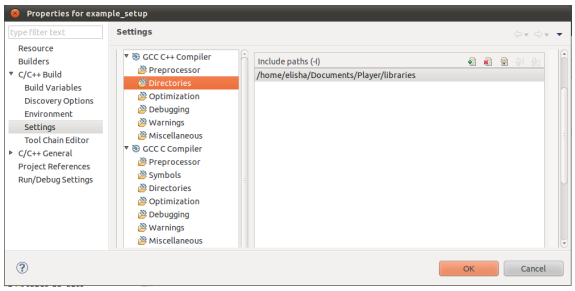

Figure B.10: Finding the location of the Player library on your system

- In the *Directories* folder for both *GCC C++ Compiler* and *GCC C Compiler* press the green plus sign and say where the player library is located on your computer
- For example, I have a copy of the library located in *Documents* inside a folder that I called *libraries*
- Your player library can be somewhere else

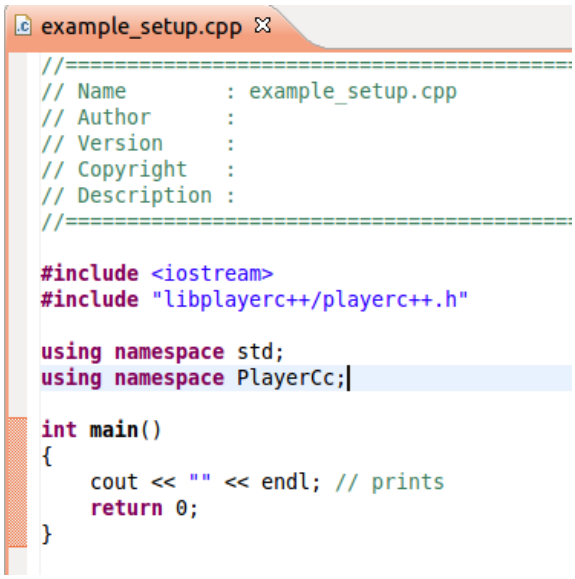

Figure B.11: Final controller window

- If there is no yellow underline after adding the line using namespace PlayerCc, then Eclipse is now set up to work with player and stage, and you can use all Player tools within its library

Appendix C

Player Library

C.1 PlayerClient Class - Functions

	Make a client and connect it as indicated PlayerClient(const std::string aHostname=PLAYER_HOSTNAME, uint aPort=PLAYER_PORTNUM, int transport=PLAYERC_TRANSPORT_TCP
	Destructor ~ PlayerClient ()
void	**Start the run thread** StartThread ()
void	**Stop the run thread** StopThread ()
void	**This starts a blocking loop on Read()** Run ()
void	**Stops the Run() loop** Stop ()
bool	**Check whether there is data waiting on the connection, blocking for up to timeout milliseconds (set to 0 to not block)** Peek (uint timeout=0)
void	**Set connection retry limit, which is the number of times that we'll try to reconnect to the server after a socket error** SetRetryLimit (int limit)
int	**Get connection retry limit, which is the number of times that we'll try to reconnect to the server after a socket error** GetRetryLimit (int limit)

void	**Set connection retry time, which is number of seconds to wait between reconnection attempts** SetRetryTime (double time)
double	**Get connection retry time, which is number of seconds to wait between reconnection attempts** GetRetryTime (double time)
void	**A blocking Read** Read ()
void	**A nonblocking Read** ReadIfWaiting ()
void	**Set whether the client operates in Push/Pull modes** SetDataMode (uint aMode)
void	**Set a replace rule for the clients queue on the server** SetReplaceRule (bool aReplace, int aType=-1, int aSubtype=-1, int aInterf=-1)
void	**Get the list of available device ids.** RequestDeviceList ()
std::string	**Returns the hostname** GetHostname () const
int	**Returns the port** GetPort () const
int	**Get the interface code for a given name** LookupCode (std::string aName) const
std::string	**Get the name for a given interface code** LookupName (int aCode) const

C.2 Position2dProxy Class - Functions

	Constructor Position2dProxy (PlayerClient *aPc, uint aIndex=0)
	Destructor ~ Position2dProxy ()
void	**Send a motor command for velocity control mode** SetSpeed (double aXSpeed, double aYSpeed, double aYawSpeed)
void	**Same as the previous SetSpeed(), but doesn't take the yspeed speed (so use this one for non-holonomic robots).** SetSpeed (double aXSpeed, double aYawSpeed)
void	**Send a motor command for velocity/heading control mode** SetVelHead (double aXSpeed, double aYSpeed, double aYawHead)
void	**Same as the previous SetVelHead(), but doesn't take the yspeed speed (so use this one for non-holonomic robots)** SetVelHead (double aXSpeed, double aYawHead)
void	**Send a motor command for position control mode** GoTo (pose, vel)
void	**Same as the previous GoTo(), but doesn't take speed** GoTo (pose)
void	**Same as the previous GoTo(), but only takes position arguments, no motion speed setting** GoTo (double aX, double aY, double aYaw)
void	**Sets command for carlike robot** GoTo SetCarlike (double aXSpeed, double aDriveAngle)

void	**Get the device's geometry; it is read into the relevant class attributes** RequestGeom ()
void	**Accessor for the pose (fill it in by calling RequestGeom)** GetPose ()
void	**Enable/disable the motors** SetMotorEnable (bool enable)
void	**Reset odometry to (0,0,0)** ResetOdometry ()
void	**Sets the odometry to the pose (x, y, yaw)** SetOdometry (double aX, double aY, double aYaw)
double	**Accessor method** GetXPos () const
double	**Accessor method** GetYPos () const
double	**Accessor method** GetYawPos () const
double	**Accessor method** GetXSpeed () const
double	**Accessor method** GetYSpeed () const
double	**Accessor method** GetYawSpeed () const
bool	**Accessor method** GetStall () const

C.3 SonarProxy Class

	Constructor SonarProxy (PlayerClient *aPc, uint aIndex=0)
	Destructor ~ SonarProxy ()
int	**Return the sensor count** GetCount () const
double	**Return a particular scan value** GetScan (uint aIndex) const
double	**This operator provides an alternate way to access the scan data** operator[] (uint aIndex) const
int	**Number of valid sonar poses.** GetPoseCount () const
double	**Sonar poses (m,m,radians)** GetPose (uint aIndex) const
void	**Request the sonar geometry** RequestGeom ()

24  * Dr. Robot X80 Driver for Player/Stage
25  */
26
27
28 /** @ingroup drivers */
29 /** @{ */
30 /** @defgroup driver_x80 x80
31  * @brief Dr Robot X80 platform
32
33 The X80 platform used at DRDC Ottawa uses a PMS5005 Robot Sensing/
      Motion Controller
34 and the PMB5010 Robot Multimedia Controller to drive the X80 robot and
      communicate
35 with its onboard sensors.  Implemented in this driver will be the
      motion control,
36 and feedback from the 7 IR sensors and 6 Sonar sensors mounted around
      the vehicle.
37 Sensor data is passed through a low pass filter when it arrives --
      setting the
38 smoothing factor (\alpha) to 1 effectively removes the filter
39
40 @par Compile-time dependencies
41
42 - none
43
44 @par Provides
```

```
45
46 The x80 driver provides the following device interfaces, some of
47 them named:
48
49 - @ref interface_position2d
50   - This interface returns position and velocity data, and accepts
       velocity commands,
51     and commands to set the velocity PID gains.
52   - PLAYER_POSITION2D_DATA_STATE
53   - PLAYER_POSITION2D_DATA_GEOM
54
55 - @ref interface_sonar:0
56   - This interface returns the Sonar range data.
57     - PLAYER_SONAR_DATA_RANGES
58     - PLAYER_SONAR_DATA_GEOM
59
60 - @ref interface_sonar:1
61   - This interface returns the IR range data -- the sonar interface is
       used for compatibility with Stage
62     - PLAYER_SONAR_DATA_RANGES
63     - PLAYER_SONAR_DATA_GEOM
64
65 @par Supported configuration requests
66
67 - @ref interface_position2d :
68   - PLAYER_POSITION2D_REQ_SET_ODOM
69   - PLAYER_POSITION2D_REQ_RESET_ODOM
70   - PLAYER_POSITION2D_REQ_GET_GEOM
71   - PLAYER_POSITION2D_REQ_MOTOR_POWER
72
73 - @ref interface_sonar : 0-1
74   - PLAYER_SONAR_REQ_GET_GEOM
75
76 @par Supported commands
77
78 - @ref interface_position2d :
79   - PLAYER_POSITION2D_CMD_VEL
80   - PLAYER_POSITION2D_REQ_SPEED_PID
81
82
83 @par Configuration file options
84
85 - address (string) -- serial port for serial connection or ip address
     for UDP connection
86   - Default: "/dev/ttyS0"
87
88 - connection (string) -- "serial" or "udp"
89   - Default: "serial"
90
91 - port (int) -- socket to communicate with the x80, only valid with udp
       connection
92   - Default: 10001
93
94 - pose (tupleFloat) -- initial odometry pose for the vehicle
```

```
95   - Default (0,0,0,0)
96
97 - sonar_filter(float) -- smoothing factor for sonar data
98   - Default 1.0
99
100 - ir_filter(float) -- smoothing factor for ir data
101   - Default 1.0
